Abstract

We examine the asymptotic properties of the QMLE for the $\mathrm{GQARCH}\,(1,1)$ model. Under suitable conditions, we establish that the asymptotic distribution of $n^{\frac{a-1}{a}}\,(\mathrm{QMLE} - \theta_0)$ for θ_0 the true parameter, is the one of the unique minimizer of a quadratic form over a closed and convex subset of $\mathbb{R}^4$. This form is the squared distance (w.r.t. a p.d. matrix) to a random vector that follows a normal distribution when $a = 2$ or is a linear transformation of an a-stable random vector when $a \in (1,2)$. This implies that we have distributional convergence to this random vector when θ_0 is an interior point. Hence we obtain cases in which non normal limit distributions are obtained either due to convergence of the estimator on the boundary of the parameter space, and/or due to the non existence of high order moments for random elements involved in this framework. Possible extensions concern the establishment of analogous results for indirect estimators based on the QMLE which could have desirable first order asymptotic properties.

KEYWORDS: Conditional heteroskedasticity, quadratic ARCH models, stochastic recurrence equation, stationarity, ergodicity, quasi likelihood, normal integrand, epi-convergence, martingale CLT, $\mathrm{CLT}''s$ to a-stable distributions, inner limit of set sequences, weak convergence to minimizers of quadratic forms over closed convex sets.

JEL: C10, C13.

1 Introduction

We examine the asymptotic properties of the QMLE for the $\mathrm{GQARCH}\,(1,1)$ model. The latter falls into the general class of quadratic ARCH models which was introduced in 1995 by Sentana [14]. This provided the most general formulation of any element of the conditional variance process as a (non anticipative) quadratic function of elements of the GQARCH process itself. This formulation allows for the representation of negative dynamic asymmetry (partly attributed to the so called "leverage effect") that is an empirical stylized fact of financial time series.

Our motivation stems from the fact that even though the analogous properties of the QMLE have been studied for a wide class of conditionally heteroskedastic models, this model was not included in any of these results. See inter alia Straumann [12] for a treatment of the $\mathrm{AGARCH}\,(p,q)$ model, Berkes et al. [2] for the $\mathrm{GARCH}\,(p,q)$ model and Wintenberg and Cai for the $\mathrm{EGARCH}\,(1,1)$ model. Our methodology allows for cases where the true parameter vector lies on the boundary of the parameter space and/or the random variables of the innovation process upon which the conditional variance process is constructed do not possess finite fourth moments. The asymptotic theory of M-estimators when the true parameter lies on the boundary has already been studied in the context of the $\mathrm{GARCH}\,(p,q)$ model in the more general work of Andrews [1]. Our considerations involve a slightly different approach for the approximation of the sequence of translated and normalized parameter spaces that is *not less general* than the previous.

The limit theory for the QMLE in the context of the $\mathrm{GARCH}\,(p,q)$ with non existing fourth order moments for the innovation process was studied in Mikosch and Straumann [7] that extended the work of Hall and Yao [4]. They obtain their results by deriving a CLT to stable laws for martingale transforms[1] satisfying (among others) a mixing condition (condition $\mathcal{A}\,(a_n)$ in their terminology). As they point out (see the first paragraph of page 495) the main difficulty of their approach lies in the verification of the mixing conditions implying $\mathcal{A}\,(a_n)$ for other models of conditional heteroskedasticity apart from $\mathrm{GARCH}\,(p,q)$. In our case we avoid this difficulty by instead relying on Theorem B.1 of Surgailis [13]. This along with the Cramer-Wold device, provides a CLT to stable laws in which *the mixing condition of the previous result can be replaced by ergodicity* for the stationary and adopted process in the martingale transform. We notice that the last requirement is *readily* verified in our case since it involves the establishment of ergodicity for the derivatives w.r.t. parameters of the volatility process. Such results can be obtained via Theorem 2.6.1 of Straumann [12] thereby straightforward establishing a non standard rate and a stable limit law. We note that this approach can be also used for the verification of analogous results in other conditionally heteroskedastic models where ergodicity is easier to establish than mixing.

Our methodology and the remaining structure of the paper is as follows. We first present the model and discuss how the chosen parameterization enables the subsequent approach. Secondly, using the stochastic recurrence equation (SRE) theory as in Straumann [12], we provide sufficient conditions for the existence of a unique stationary ergodic solution to the associated recurrence relation and prove that there exist (among others weakly non stationary) $\mathrm{GQARCH}\,(1,1)$ processes for which these are satisfied. The presence of the autoregressive parameter in the conditional variance SRE complicates the issue of the derivation of tighter conditions, yet the consideration of the QARCH case provides us with some directions for future research.

Third, given the previous we define the usual in applications version of the quasi likelihood function emerging from filtering the volatility by arbitrary initial conditions and its stationary and ergodic approximation. We show that these functions are P a.s. twice differentiable on the largest subset of $\mathbb{R}^4$ for which the model is well defined, even in cases where the associated partial derivatives are obtained by one sided partial differentiation as in Andrews [1]. Given results concerning approximations of the non stationary by the stationary and ergodic likelihoods and their derivatives, and via the use of an LLN concerning stationary and ergodic random functions

---

[1]This terminology is in some cases $(a<1)$ inaccurate as they point out in section 3 of their paper.

which may attain the value $+\infty$, and then the use of a CLT for stationary and ergodic martingale differences when finite fourth moments exist, or of the CLT to an a-stable random vector (briefly described previously) when finite absolute moments of some order in $(3, 4)$ exist, we show first consistency and then that the rate of convergence is $n^{\frac{a-1}{a}}$ for $a = 2$ and $a \in (1, 2)$ in the first and second case respectively.

Finally, when the parameter space can be suitably approximated by some closed and convex subset of $\mathbb{R}^4$, we obtain via the use of Lemma 7.13 of van der Vaart [16] that the asymptotic distribution of $n^{\frac{a-1}{a}} \left(\mathrm{QMLE} - \theta_0 \right)$ is characterized as the one of the unique minimizer over that set of a quadratic form w.r.t. a p.d. matrix and a random vector that follows a normal distribution when $a = 2$ or is a linear transformation of an a-stable random vector when $a \in (1, 2)$. We conclude by posing some questions for future research emerging from our results. The proofs of the main propositions are presented in the main body of the paper. Several auxiliary technical lemmas are presented in the appendix.

2   Model Specification

In the following let $(\Omega, \mathcal{F}, P)$ denote a complete probability space and Θ a non empty subset of the Euclidean space $\mathbb{R}^4$. Any concept of measurability is in any case handled w.r.t. to $\mathcal{F}$, the Borel σ-fields of $\mathbb{R}$, $\mathbb{R}^n$, $\mathbb{R}^{\mathbb{Z}}$ (the latter w.r.t. the product topology) and Θ or where appropriate w.r.t. analogous product σ-fields. Notice that separability and completeness imply measurability of $\inf_A \|\cdot\|$ where A is either $\mathbb{R}^{\mathbb{Z}}$ or any sequentially complete subset of Θ. Let $z : \Omega \to \mathbb{R}^{\mathbb{Z}}$ be an iid sequence of random variables, with $\mathbb{E}z_0 = 0$, and $\mathbb{E}z_0^2 = 1$. Define the volatility process $(\sigma_t^2)_{t \in \mathbb{Z}}$ as any ($\mathbb{Z}$ indexed) sequence of non negative random variables satisfying the following first order stochastic recurrence equation (see Sentana [14])

$$\sigma_t^2 (\theta) = \omega + \alpha \left(z_{t-1} \sigma_{t-1} (\theta) + \frac{\gamma}{2\alpha} \right)^2 + \beta \sigma_{t-1}^2 (\theta) \tag{1}$$

where $\theta = (\omega, \alpha, \gamma, \beta)' \in \Theta$. *Given* the existence of $(\sigma_t^2)_{t \in \mathbb{Z}}$ construct the $\mathrm{GQARCH}(1, 1)$ process $(y_t)_{t \in \mathbb{Z}}$ by

$$y_t = z_t \sigma_t$$

In the following paragraph we provide some justification for the choice of parameterization in (1), and simultaneously specify Θ as the largest subset of $\mathbb{R}^4$ so that any process satisfying (1) is well defined (i.e. σ_t^2 is finite and non-negative P a.s. for any t) *and* the methodology used for the derivation of asymptotic properties is valid.

Parameter Restrictions-Positivity Constraints.   A necessary condition for the existence of a solution to (1) is that σ_t^2 is finite and non-negative P a.s. for any t. We easily obtain from the analogous $\mathrm{GARCH}(1, 1)$ case and the choice of parameterization in (1) that non negativity holds strictly iff $\omega > 0$, $\alpha > 0$, $\beta \geq 0$. Notice that this encompasses *neither* the case of non random, yet time varying volatility *nor* the one of homoskedasticity since the choice $\alpha = 0$ is obviously not allowed. A reformulation of (1) so as to contain the case of $\alpha = 0$ could be obtained if we specified $\sigma_t^2 = \omega + \beta \sigma_{t-1}^2$ when $\alpha = 0$, hence impose the convention that when $\alpha = 0$ then $\gamma = 0$ and furthermore that $\frac{0}{0} = 0$. This however would invalidate the methods used

for the determination of the rates of convergence and the asymptotic distribution of the QMLE below.[2]

We could have considered two alternative parameterizations of (1) so as to disentangle this restriction. The first one would be $\sigma_t^2 = \omega^* + \alpha^* z_{t-1}^2 \sigma_{t-1}^2 (\theta) + \gamma^* z_{t-1}\sigma_{t-1} + \beta \sigma_{t-1}^2$. In this case it is already known from Sentana [14] that strict positivity P a.s. for any t holds iff $\omega^* > 0$, $\alpha^* \geq 0$, $\beta^* \geq 0$ and $\omega^* \alpha^* > \frac{(\gamma^*)^2}{4}$ when $\alpha^* > 0$ and $\gamma^* = 0$ when $\alpha^* = 0$. This case obviously invalidates lemma 2.1 below. The second one would be $\sigma_t^2 = \omega_* + \alpha_* (z_{t-1}\sigma_{t-1} + \gamma_*)^2 + \beta_* \sigma_{t-1}^2$. For this strict positivity P a.s. for any t holds iff $\omega_* > 0$, $\alpha_* \geq 0$, $\beta_* \geq 0$. In this case when $\alpha_* = 0$ if γ_* assumes more than one values then it remains non identified. This problem is fixed if γ_* assumes one value (say 0). Notice however that the derivatives of the volatility process w.r.t. γ_* (or γ^* in the previous case) evaluated at any point of the form $(\omega_*, 0, 0, 0)'$ would be identically zero, rendering the methodology used given consistency invalid. Hence we stick with the parametrization in (1) and restrict $\alpha > 0$. This restriction implies that the asymptotic properties of the QMLE in any of the last two parameterizations can be directly recovered by the analogous properties of the QMLE in the case considered via the continuous mapping theorem and the delta method (which generally goes through by Theorem 20.8 of van der Vaart [16]).

Furthermore, we allow γ to assume only non positive values, something that is in accordance to the empirical stylized fact of the leverage effect in financial time series. Hence this constraint has *econometric significance*. Finally in order to facilitate the following result (first among others) we further constrain β to be strictly less than 1. Given the previous we define the eligible parameter space as

$$\Theta = \mathbb{R}^{++} \times \mathbb{R}^{++} \times \mathbb{R}^{-} \times [0,1)$$

In what follows the inference procedures to be examined will be defined so as to employ compact subsets of Θ. The following result is quite useful. It states that for any $\theta \in \Theta$ the volatility process is bounded away from zero.

Lemma 2.1 *If for some $\theta \in \Theta$ there exists a volatility process satisfying (1) then* $\inf\limits_{z \in \mathbb{R}^{\mathbb{Z}}} \sigma_t^2 \geq \frac{\omega}{1-\beta} \ \forall t \in \mathbb{Z}$.

Proof. Minimizing $\omega + \alpha \left(z_{t-1}\sigma_{t-1}(\theta) + \frac{\gamma}{2\alpha} \right)^2 + \beta \sigma_{t-1}^2 (\theta)$ given σ_{t-1}^2 we obtain

$$\inf\limits_{z_{t-1} \in \mathbb{R}} \sigma_t^2 = \omega + \beta \sigma_{t-1}^2$$

Proceeding recursively the result follows. ∎

Existence-Stationarity-Ergodicity. Given the construction of Θ, we use the SRE approach in Straumann [12] in order to show that there exist elements of Θ for which (1) assumes

---

[2]If we had adopted this reformulation then given the framework (to be defined later) of the auxiliary volatility process and the likelihood function we have that the latter would remain a P a.s. lower semicontinuous function and the arguments in the proof of proposition 3.5 would remain intact. Hence the QMLE would be consistent even when $\theta_0 = (\omega_0, 0, 0, \beta_0)$ except for the case where $\beta_0 \neq 0$ since this would obviously invalidate lemma 3.3. Then it is easy to see that for $\theta_0 = (\omega_0, 0, 0, 0)$ lemma 3.6 would not hold (the likelihood function would not posses Frechet derivatives at θ_0) hence the subsequent methodology would break down.

a unique stationary ergodic solution.[3] From (1) and lemma 2.1 it is obvious that

$$\sigma_t^2 = \phi_t\left(\sigma_{t-1}^2\right), \quad t \in \mathbb{Z}$$

where $\phi_t : \left[\frac{\omega}{1-\beta}, \infty\right) \to \left[\frac{\omega}{1-\beta}, \infty\right)$ with

$$\phi_t(s) = \omega + \alpha\left(z_{t-1}\sqrt{s} + \frac{\gamma}{2\alpha}\right)^2 + \beta s.$$

Due to the properties of z and Proposition 2.1.1 of Straumann [12] this specifies a stationary ergodic sequence of random maps and the

$$\Lambda\left(\phi_t\right) = \sup_{s \in \left[\frac{\omega}{1-\beta}, \infty\right)} \left| \alpha z_{t-1}^2 + \beta + \frac{\gamma z_{t-1}}{2\sqrt{s}} \right| < \infty.$$

specifies the analogous stationary ergodic sequence of their random Lipschitz coefficients.

Lemma 2.2 $\mathbb{E}\left[\ln^+ \Lambda\left(\phi_t\right)\right] < \infty.$

Proof. Observe that $\Lambda\left(\phi_t\right) \leq \alpha z_{t-1}^2 + \beta + \sup_{x \in \left[\frac{\omega}{1-\beta}, \infty\right)} \frac{-\gamma|z_{t-1}|}{2\sqrt{x}}$ which, due to Lemma 2.1, equals

$\alpha z_{t-1}^2 + \beta + \frac{-\gamma|z_{t-1}|}{2\sqrt{\frac{\omega}{1-\beta}}} < \infty.$ Hence, $\mathbb{E}\Lambda\left(\phi_t\right) < \infty$ which completes the proof. ■

Hence by Theorem 2.6.1 of Straumann [12], and Lemma 2.2, the SRE (1) admits a unique stationary ergodic solution $\left(\sigma_t^2\right)_{t \in \mathbb{Z}}$ when $\theta \in \Theta \cap \{\theta : \mathbb{E}\left[\ln \Lambda\left(\phi_t\right)\right] < 0\}$ which has the P a.s. representation

$$\sigma_t^2(\theta) = \lim_{m \to \infty} \phi_{t-1} \circ ... \circ \phi_{t-m}(y), \quad t \in \mathbb{Z} \tag{2}$$

Furthermore by Proposition 2.1.1 of Straumann [12] $(y_t)_{t \in \mathbb{Z}}$ is also stationary ergodic.

The following remark implies that there exist elements of Θ for which $\mathbb{E}\left[\ln \Lambda\left(\phi_t\right)\right] < 0$ and furthermore that some of them imply second order *non* stationarity for the $\mathrm{GQARCH}\left(1,1\right)$ process.

Remark R.1 *From the analogous results for the* $\mathrm{GARCH}\left(1,1\right)$ *we know that there exist* $\alpha > 0$, $\beta > 0$ *so that the corresponding volatility process is stationary ergodic (see Nelson [9]). Let such a pair of* (α, β). *Now* $\sup_{s \in \left[\frac{\omega}{1-\beta}, \infty\right)} \left| \alpha z^2 + \beta + \frac{\gamma z}{2\sqrt{s}} \right| \leq \alpha z^2 + \beta - \frac{\gamma|z|}{2\sqrt{\frac{\omega}{1-\beta}}} \leq \alpha z^2 + \beta -$

$\frac{\gamma\left(1+z^2\right)}{2\sqrt{\frac{\omega}{1-\beta}}} = \left(\alpha - \frac{\gamma}{2\sqrt{\frac{\omega}{1-\beta}}}\right) z^2 + \left(\beta - \frac{\gamma}{2\sqrt{\frac{\omega}{1-\beta}}}\right).$ *Then due to the continuity of* $\mathbb{E}\ln\left(\alpha z_0^2 + \beta\right)$ *in* (α, β) *and Jensen's inequality there exist* ω *and* γ *(that can be chosen strictly negative) so that* $\mathbb{E}\ln\left(\alpha z_0^2 + \beta\right) < 0$ *implies that*

$$\mathbb{E}\ln\left(\left(\alpha - \frac{\gamma}{2\sqrt{\frac{\omega}{1-\beta}}}\right) z^2 + \left(\beta - \frac{\gamma}{2\sqrt{\frac{\omega}{1-\beta}}}\right)\right) < 0.$$

---

[3]Uniqueness holds in the sense that any other solution belongs to the same equivalence class w.r.t. the exponentialy almost sure (w.r.t. P) convergence as $t \to \infty$. See Straumann [12], Theorem 2.6.1.

Finally notice that from the results for the $\mathrm{GARCH}\,(1,1)$ case α and β can be chosen so that $\alpha + \beta \geq 1$. Hence there exist $\theta \in \Theta$ for which $\mathbb{E}\left[\ln \Lambda\left(\phi_t\right)\right] < 0$ that imply first order non stationarity for the volatility process (hence covariance non stationarity for the $\mathrm{GQARCH}\,(1,1)$ process).

The next remark implies that the condition described above can be restrictive. It concerns the $\mathrm{QARCH}\,(1)$ case.

Remark R.2 *Suppose that $\beta = 0$, then the condition $\mathbb{E}\ln\left(\alpha z_0^2\right) < 0$ (which is also necessary and sufficient condition for the existence and uniqueness of stationary and ergodic solution in the $\mathrm{ARCH}\,(1)$ case) is sufficient. To see this, consider the SRE describing the squared root of the conditional variance process in the $\mathrm{QARCH}\,(1)$ case, i.e.*

$$\sigma_t = \phi_t\left(\sigma_{t-1}\right), \quad t \in \mathbb{Z}$$

with $\phi_t\left(s\right) = \left[\omega + \alpha\left(z_{t-1}s + \frac{\gamma}{2\alpha}\right)^2\right]^{1/2}$. Then $\left|\phi_t'\left(s\right)\right| = \left|\frac{\sqrt{\alpha}\left(z_{t-1}s + \frac{\gamma}{2\alpha}\right)}{\phi_t(s)}\right|\sqrt{\alpha}\left|z_{t-1}\right| \leq \sqrt{\alpha}\left|z_{t-1}\right|$

*since $\left|\frac{\sqrt{\alpha}\left(z_{t-1}s + \frac{\gamma}{2\alpha}\right)}{\phi_t(s)}\right| = \sqrt{\frac{\alpha\left(z_{t-1}s + \frac{\gamma}{2\alpha}\right)^2}{\omega + \alpha\left(z_{t-1}s + \frac{\gamma}{2\alpha}\right)^2}} < 1$ as $\omega > 0$. This along with partial evidence from simulations lead us to **conjecture** that the necessary and sufficient condition for existence and uniqueness of stationary and ergodic solution for the $\mathrm{GARCH}\,(1,1)$ model, i.e. $\mathbb{E}\ln\left(\alpha z_0^2 + \beta\right) < 0$, is also sufficient for the $\mathrm{GQARCH}\,(1,1)$ model.*

Notation: *In the following θ_0 signifies an arbitrary member of Θ for which there exists a unique stationary ergodic solution to (1). The previous remarks imply that θ_0 exists, and that it can belong to either the interior or the boundary of Θ.*

3   The QMLE and its Limit Theory

We are interested in the behavior of the QMLE for θ_0. We restate known ergodic and non ergodic versions of the Quasi Likelihood function based on volatility filters (auxiliary volatility processes) constructed from the GQARCH process and the form of the SRE in (1). In the first case the filter is defined on $\mathbb{Z}$ whereas in the second one it is assumed to stem from an arbitrary initial condition posed on the same SRE.

In any of the two cases it is easily deduced that the necessary condition of finiteness and non-negativity P a.s. for any t, for the existence of processes that satisfy the analogous SRE (or the initial condition problem) are satisfied due to the definition of Θ (see the discussion in paragraph 2). Obviously only the QMLE associated with the second case is practically feasible.

Auxiliary Ergodic Volatility Process and the Ergodic Quasi Likelihood Function. We first consider the ergodic case.

Definition D.1 *For any $\theta \in \Theta$ and given $\left(y_i\left(\theta_0\right)\right)_{t\in\mathbb{Z}}$ define the random element $\left(h_t\right)_{t\in\mathbb{Z}}$ by the following SRE*

$$h_t = \omega + \alpha\left(y_{t-1}\left(\theta_0\right) + \frac{\gamma}{2\alpha}\right)^2 + \beta h_{t-1}.$$

Lemma 3.1 *The previous P a.s. admits a unique stationary and ergodic solution $(h_t)_{t \in \mathbb{Z}}$ of the form*

$$h_t = \frac{\omega}{1-\beta} + \alpha \sum_{i=0}^{\infty} \beta^i \left(y_{t-1-i}(\theta_0) + \frac{\gamma}{2\alpha} \right)^2 .$$

Moreover $\inf_K \inf_{y \in \mathbb{R}^{\mathbb{Z}}} h_t(\theta) > 0$ and independent of t for K any compact subset of Θ.

Proof. It follows from the definition of Θ, Proposition 5.2.12 of Straumann [12] and lemma 2.1.
∎

The following defines the (infeasible w.r.t. applications) Quasi Likelihood function. The term is used in an abusive manner since the original function would be constructed as $-\frac{1}{2} * c_n(\theta) + \mathrm{const}$. This form enables the characterization of the QMLE as a minimizer.

Definition D.2 *The ergodic version of the quasi likelihood function for the $\mathrm{GQARCH}(1,1)$ process is*

$$c_n(\theta) = \frac{1}{n} \sum_{i=1}^{n} \ell_i(\theta)$$

where

$$\ell_i(\theta) = \ln h_i(\theta) + \frac{y_i^2(\theta_0)}{h_i(\theta)}.$$

Remark R.3 *c_n is continuous on Θ due to the previous lemma, and jointly measurable, hence when restricted to any compact subset of Θ (say K) it is a normal integrand in the sense of definition 3.5 of Molchanov [8]. Also due to the ergodicity of σ_t^2 and h_t, c_n defines an ergodic process for any θ.*

Non Ergodic Volatility Process and the non Ergodic Quasi Likelihood Function. We study versions of the processes in the previous definitions emerging from arbitrary initial conditions. In this stationarity and ergodicity are lost but feasibility w.r.t. applications is obtained.

Definition D.3 *For any $\theta \in \Theta$ and given $(y_i(\theta_0))_{t \in \mathbb{Z}}$ define the random element $(h_t)_{t \geq 0}$ by the following*

$$h_t^*(\theta) = \begin{cases} \varsigma_0^2 & \text{if } t = 0 \\ \omega + \alpha \left(y_{t-1} + \frac{\gamma}{2\alpha} \right)^2 + \beta h_{t-1}^*(\theta) & \text{if } t \geq 1 \end{cases}$$

for some positive random variable ς_0 where again $\theta = (\omega, \alpha, \gamma, \beta)' \in \Theta$.

Remark R.4 *Obviously $(h_t^*)_{t \geq 0}$ is well defined but generally non stationary. Also $\inf_K \inf_{y \in \mathbb{R}^{\mathbb{Z}++}} h_t^*(\theta) > 0$ and independent of t for K any compact subset of Θ.*

Definition D.4 *The non ergodic version of the quasi likelihood function for the $\mathrm{GQARCH}(1,1)$ process is*

$$c_n^* (\omega, \theta) = \frac{1}{n} \sum_{i=1i}^{n} \ell_i^* (\theta)$$

where

$$\ell_i^* (\theta) = \ln h_i^* (\theta) + \frac{y_i^2 (\theta_0)}{h_i^* (\theta)}.$$

Remark R.5 c_n^* *is also continuous on* Θ *as well as jointly measurable, hence it is a normal integrand in the sense of definition 3.5 of* Molchanov [8] *when restricted to* K *an arbitrary compact subset of* Θ.

3.1 Existence and Consistency of the Estimator

Definition and Existence

The following assumption defines the parameter space that will be subsequently used.

Assumption A.1 K *is a compact subset of* Θ *for which* $\theta_0 \in K$.

Notice that given the definition of Θ, K could be chosen from some further available information for θ_0. The following propositions define and provide the existence for the QMLE w.r.t. the two versions of the likelihood functions presented before. We allow for the case that the estimators are approximate maximizers and thereby there exist optimization errors.

Proposition 3.2 *For an arbitrary* P *a.s. non negative random variable* ε_n *there exists a random element* θ_n *with values in* K *defined by*

$$c_n^* (\theta_n) \leq \inf_K c_n^* (\theta) + \varepsilon_n$$

Proof. The result follows by remark R.3 which renders applicable Proposition 3.12.iii and the fundamental selection theorem (Theorem 2.13) of Molchanov [8]. ∎

Notice that the continuity arguments for the existence and measurability of the estimator are essential only in the case that the optimization error is P a.s. zero.

Consistency

The following lemmas provide with an identification condition, and the existence of $\ln$ moments that enable the approximation of the non ergodic by the ergodic version of the likelihood function. They are used for the derivation of consistency. We obtain them via the use of the following assumptions.

Assumption A.2 *The distribution of* z_0 *is not concentrated in two points.*

Assumption A.3 $\mathbb{E} \ln^+ (\varsigma_0^2) < \infty$.

The first assumption implies the validity of asymptotic identification. The second, while not being very restrictive, permits the derivation of consistency for θ_n from a suitable approximation of c_n^* by c_n.

Lemma 3.3 *Under assumption* A.2 *the relation* $h_t(\theta) = h_t(\theta_0)$ P *a.s.* $\forall \theta \in K$, $\forall t$ *implies* $\theta = \theta_0$.

Proof. Towards a contradiction, suppose that there exist $\theta \neq \theta_0$, so that $h_t(\theta) = h_t(\theta_0)$ P a.s. $\forall t$. Then

$$(\omega^* - \omega_0^*) + (\alpha - \alpha_0)y_{t-1}^2 + (\gamma - \gamma_0)y_{t-1} + (\beta - \beta_0)h_{t-1} = 0 \quad \forall t$$

where we define $\omega^* = \omega + \frac{\gamma^2}{4\alpha}$ and $\omega_0^* = \omega_0 + \frac{\gamma_0^2}{4\alpha_0}$. However, this implies that h_{t-1} is at the same time a measurable function of z_{t-1} and independent of z_{t-1}. By Lemma 5.4.2 of Straumann [12] the only way for this to be possible is if h_{t-1} is constant $\forall t$ P a.s. Suppose $h_t = h$ constant. This necessarily implies that $\alpha + \beta < 1$. Taking expectations on the volatility process we must have $h = \frac{\omega^*}{1-\alpha-\beta}$. But

$$h = \omega^* + (\alpha z_0^2 + \beta)h + \gamma z_0 \sqrt{h}$$

which is equivalent to

$$z_0^2 + \left(\frac{\gamma}{\alpha} \sqrt{\frac{1-\alpha-\beta}{\omega^*}} \right) z_0 - 1 = 0$$

and this is a second order equation in z_{t-1} with positive discriminant. It has two roots, one positive and one negative. This would imply that the support of the distribution of z_0 contains exactly two points. This violates assumption A.2 thus necessarily $\beta = \beta_0$. Now the following equation

$$(\alpha - \alpha_0)y^2 + (\gamma - \gamma_0)y + (\omega^* - \omega_0^*) = 0$$

is a second order equation in y. Since $(\omega^* - \omega_0^*, \alpha - \alpha_0, \gamma - \gamma_0) \neq (0,0,0)$, there are three distinct cases concerning its roots: **i)** a single root λ of multiplicity 2, which leads to contradiction due to the facts $\mathbb{E}(y) = 0$, $\mathbb{E}(y^2) \neq 0$, **ii)** two roots of the same sign, which leads to contradiction since either $\mathbb{E}(y)$ does not exist or equals 0, and **iii)** two roots of alternating sign, in which case the contradiction is a consequence of the fact that z_t is independent of h_t and h_t is not a constant. Then necessarily $(\omega^* - \omega_0^*, \alpha - \alpha_0, \gamma - \gamma_0) = (0,0,0)$. The definition of ω^* and the fact that γ^* is non positive completes the proof. ■

The following establishes the existence of log moments for the processes of interest.

Lemma 3.4 $\mathbb{E} \ln^+ \sigma_t^2 < \infty$, $\mathbb{E} \ln^+ y_t^2 < \infty$ *and* $\mathbb{E} \ln^+ h_t(\theta) < \infty$ *for any* $\theta \in K$.

Proof. First notice that due to lemma 2.1

$$
\begin{aligned}
\sigma_t^2 &\leq \omega_0 + \frac{\gamma_0^2}{4\alpha_0} + \left(\alpha_0 z_{t-1}^2 + \beta_0 + \frac{\gamma_0 z_{t-1}}{\sigma_{t-1}} \mathbf{1}\left\{ z_{t-1} < 0 \right\} \mathbf{1}\left\{ \sigma_{t-1} \geq 2\sqrt{\frac{\omega_0}{1-\beta_0}} \right\} \right) \sigma_{t-1}^2 \\
&\quad + \gamma_0 z_{t-1} \mathbf{1}\left\{ z_{t-1} < 0 \right\} \mathbf{1}\left\{ \sigma_{t-1} < 2\sqrt{\frac{\omega_0}{1-\beta_0}} \right\} \sigma_{t-1} \\
&\leq \omega_0 + \frac{\gamma_0^2}{4\alpha_0} + \left(\alpha_0 z_{t-1}^2 + \beta_0 + \frac{\gamma_0 z_{t-1}}{2\sqrt{\frac{\omega_0}{1-\beta_0}}} \mathbf{1}\left\{ z_{t-1} < 0 \right\} \mathbf{1}\left\{ \sigma_{t-1} \geq 2\sqrt{\frac{\omega_0}{1-\beta_0}} \right\} \right) \sigma_{t-1}^2 \\
&\quad + 2\sqrt{\frac{\omega_0}{1-\beta_0}} \gamma_0 z_{t-1} \mathbf{1}\left\{ z_{t-1} < 0 \right\} \\
&\leq A_t \sigma_{t-1}^2 + C_{t-1}
\end{aligned}
$$

9

where $A_t \doteq \alpha_0 z_{t-1}^2 + \beta_0 + \frac{\gamma_0 z_{t-1}}{2\sqrt{\frac{\omega_0}{1-\beta_0}}} \mathbf{1}\{z_{t-1} < 0\} < \Lambda(\phi_t)$ and $C_{t-1} \doteq \omega_0 + \frac{\gamma_0^2}{4\alpha_0} + 2\sqrt{\frac{\omega_0}{1-\beta_0}} \gamma_0 z_{t-1} \mathbf{1}\{z_{t-1} < 0\}$.

Then from the definition of θ_0 we have that $\mathbb{E}\ln A_t \leq \mathbb{E}\ln\Lambda(\phi_t) < 0$. If we define the auxiliary SRE

$$s_t^2 = A_{t-1} s_{t-1}^2 + C_{t-1}$$

we can use similar arguments as in Example 5.2.5 of Straumann [12] to show that $\exists \eta : 0 < \eta \leq 1$ so that $\mathbb{E}\left[s_t^2\right]^\eta < \infty$. Then

$$\mathbb{E}\ln^+ \sigma_t^2 \leq \mathbb{E}\ln^+ s_t^2(\theta) \leq \frac{1}{\eta}\mathbb{E}\ln^+\left[s_t^{2\eta}\right] \leq \frac{1}{\eta}\ln^+\left[\mathbb{E}s_t^{2\eta}\right] < \infty$$

The above implies $\mathbb{E}\ln^+ y_t^2 < \infty$ as $\mathbb{E}(z_t^2) = 1$. Furthermore, $\mathbb{E}\ln^+ h_t(\theta) < \infty$ can be shown by an application of the Minkowski inequality to the P a.s. representation

$$h_t(\theta) = \frac{\omega + \frac{\gamma^2}{4\alpha}}{1-\beta} + \sum_{i=0}^{\infty} \beta^i \left(\alpha y_{t-i-1}^2 + \gamma y_{t-i-1}\right)$$

which exists due to the fact that θ_0 is ergodic and $\beta < 1$, to obtain $\mathbb{E}\left[h_t(\theta)\right]^\eta < \infty$. ∎

Given identification and existence of log moments strong consistency follows for the estimator under examination if moreover the optimization error vanishes asymptotically. The notation $\|\cdot\|_K$ denotes $\sup_K \|\cdot\|$.

Proposition 3.5 *Under assumptions A.1, A.2, A.3 and if moreover $\varepsilon_n \to 0$ P a.s. θ_n is P-strongly consistent.*

Proof. If $\mathbb{E}\ln^+(\varsigma_0^2) < \infty$ then Proposition 5.2.12 of Straumann [12] holds which implies that

$$|c_n(\theta) - c_n^*(\theta)|_K \to 0 \ P \text{ a.s.}$$

due to Part 1.(i) of the proof of Theorem 5.3.1 of Straumann [12]. Then notice that

$$
\begin{aligned}
\mathbb{E}\inf_{\theta\in K}\left|\ln h_0(\theta) + \frac{z_0^2\sigma_0^2(\theta_0)}{h_0(\theta)}\right| &\leq \inf_{\theta\in K}\left(\mathbb{E}\left|\ln h_0(\theta)\right| + \mathbb{E}\frac{\sigma_0^2}{h_0(\theta)}\right) \\
&= \mathbb{E}\left|\ln h_0(\theta_0)\right| + 1 < \infty
\end{aligned}
$$

where the last equality follows from Part 1.(iii) of the proof of Theorem 5.3.1 of Straumann [12] and $\mathbb{E}\left|\ln h_0(\theta_0)\right|$ exists due to lemma 3.4 and the fact that $h_0(\theta_0) = \sigma_0^2$ P a.s. from lemma 3.3. Second, notice that from the pointwise ergodic theorem, $c_n(\theta)$ converges almost surely to its expectation, a function with values on the extended real line, which does not assume the value $-\infty$, since by lemma 3.1 $\inf_K \inf_{y\in\mathbb{R}^\mathbb{Z}} h_t(\theta) > 0$ independent of t, and is proper due to the argument of the previous sentence. Hence, from Theorem 2.1 of Korf and Wets [6] c_n epiconverges almost surely to its expectation, which due to stationarity is $\mathbb{E}\ell_0$. Hence, due to the fact that the topology of uniform convergence is finer from the topology of epiconvergence, and due to the previous we have that c_n^* epiconverges almost surely to $\mathbb{E}\ell_0$. Therefore, due to the almost sure convergence of ε_n to zero, there exists a measurable $\Omega^* \subseteq \Omega$ with $P(\Omega^*) = 1$ such that for any $\omega \in \Omega^*$, Theorem 7.31 of Rockafellar and Wets [11] implies that

$\limsup_{n\to\infty} (\varepsilon_n - \arg\min_K)(c_n^*) \subseteq \arg\min_K (\mathbb{E}\ell_0).$[4] Due to lemma 3.3 we have that for all $\omega \in \Omega$ $\arg\min_K (\mathbb{E}\ell_0) = \{\theta_0\}$ which implies $\lim_{n\to\infty} (\varepsilon_n - \arg\min_K)(c_n^*) = \{\theta_0\}$, P a.s. since by proposition 3.2 θ_n exists and belongs to $(\varepsilon_n - \arg\min_K)(c_n)$. ∎

3.2 Rate of Convergence

Given consistency, we establish the first order asymptotic properties of the estimator via the use of local quadratic approximations of the likelihood functions. These are enabled by the existence of first and second order (possibly one sided) partial derivatives of c_n and c_n^* at θ_0 and/or neighboring points, which are well defined even in cases where θ_0 is a boundary point of Θ, due to the form of Θ and the definitions of the likelihood functions and the volatility filters. Then the quadratic approximations emerge from second order Taylor expansions of the likelihoods in neighborhoods of θ_0 and remain valid when restricted to random elements assuming their values in K, even though the remainders may depend on random elements assuming values in compact subsets of Θ that contain θ_0 but are not subsets of K. In the following for $\delta > 0$, $C(\theta, \delta)$, and $S(\theta, \delta)$ denote the open cube and the sphere in $\mathbb{R}^4$ centered at θ respectively.

In what follows we partially differentiate w.r.t. θ when perceived as a member of Θ. The vector of first order partial (possibly one sided) derivatives is denoted by c_n' (resp. $c_n'^*$) and the matrix of second order partial derivatives by c_n'' (resp. $c_n''^*$). The vector of first order partial derivatives is denoted by c_n' (resp. $c_n'^*$) and the matrix of second order partial derivatives by c_n'' (resp. $c_n''^*$). Their forms are well known in the literature concerning the asymptotic theory for the QMLE in GARCH type models. We denote with $\ell_t(\theta)$, and $h_t'(\theta)$ (resp. $\ell_t'^*(\theta)$ and $h_t'^*$) and $\ell_t''(\theta)$ and $h_t''(\theta)$ (resp. $\ell_t''^*(\theta)$ $h_t''^*$) the analogous structures concerning the derivatives of the random variables $\ell_t(\theta)$ and h_t (resp. $\ell_t(\theta)$ and h_t^*) w.r.t. θ on K^+. These are explicitly derived and used in the appendix for the establishment of several intermediate results. The arguments of the previous paragraph are based on the following lemma.

Lemma 3.6 *Assumption* 2^{2^*}*(a) of Andrews* [1] *holds for* Θ.

Proof. When θ_0 belongs to the interior of Θ, choose $\delta < \inf \|\theta_0 - y\|$ where the infimum is taken w.r.t. the boundary points of Θ and it is strictly positive since the boundary is a closed set. Let (in the notation of Assumption 2^{2^*}) $K^+ = C(\theta_0, \delta)$ and notice that $K^+ - \theta_0 = C(0, \delta)$ and then for any $\delta^* < \delta$ $S(\theta_0, \delta^*) \subset C(\theta_0, \delta)$. When θ_0 belongs to the interior of Θ, choose $K^+ = C(\theta_0, \delta) \cap \Theta$ for arbitrary δ and notice that $K^+ - \theta_0$ is the intersection of $\mathbb{R}^4$ with $C(0, \delta)$ and then for any $\delta^* < \delta$, $S(\theta_0, \delta^*) \subset K^+$. ∎

We establish the rate of convergence for θ_n. This given the previous lemma essentially depends on the differentiability (possibly in the sense of Theorem 6 of Andrews [1] which is enabled via the previous lemma and definitions D.1, D.2, D.3 and D.4) of the likelihoods w.r.t. $\theta \in \Theta$, their proximity and particular properties of the stationary distribution of the innovation process. The following lemma enables the main proposition of the present section. This result will obviously be also used for the establishment of the asymptotic distribution. We denote convergence in distribution with $\rightsquigarrow$.

---

[4]Notice that the P a.s. continuity of c_n and the mode of convergence implies the lower semicontinuity of $\mathbb{E}\ell_0$ (see proposition 7.4.a of Rockafellar and Wets [11]). This along with the compactness of K imply that $\inf_K \mathbb{E}\ell_0$ is well separated.

Lemma 3.7 i) *Under assumption A.2 , if $\mathbb{E}z_0^4 < +\infty$ then $\sqrt{n}c_n'(\theta_0) \xrightarrow{d} V_2 \sim N(\mathbf{0},\mathbf{G}_0)$ as $n \to \infty$ where $\mathbf{G}_0 = (\mathbb{E}z_t^4 - 1)\mathbf{J}$ and $\mathbf{J}$ a positive definite matrix defined in lemma 4.6.*
ii) *If $P\left(z_0 \in \left[-\sqrt{x+1}, \sqrt{x+1}\right]\right) = 1 - \frac{c_2 + o(1)}{x^a}h(x)$ as $x \to +\infty$, for $c_2 > 0$, $a \in (1,2)$ and h a slowly varying function at infinity (in the Karamata sense),[5] then $n^{\frac{a-1}{a}}c_n'(\theta_0) \rightsquigarrow -V_a$ where V_a follows an a-stable distribution on $\mathbb{R}^4$ characterized as follows: for any non zero $\lambda \in \mathbb{R}^4$ $\lambda^T V_a$ follows an a-stable distribution on $\mathbb{R}$ with characteristic function $f_{\lambda^T c_a}(\theta) = \exp\left(-c(\lambda)|\theta|^a\left(1 - i\beta(\lambda)\operatorname{sgn}(\theta)\tan\left(\frac{\pi a}{2}\right)\right)\right)$ where $c(\lambda) = -\frac{\Gamma(2-a)}{a-1}c_2\cos\left(\frac{\pi a}{2}\right)\mathbb{E}\left(\left|\lambda^T \frac{h_t'(\theta_0)}{\sigma_t^2}\right|^a\right)$ and $\beta(\lambda) = -\frac{\mathbb{E}\left(\left|\lambda^T \frac{h_t'(\theta_0)}{\sigma_t^2}\right|^a \operatorname{sgn}\left(\lambda^T \frac{h_t'(\theta_0)}{\sigma_t^2}\right)\right)}{\mathbb{E}\left(\left|\lambda^T \frac{h_t'(\theta_0)}{\sigma_t^2}\right|^a\right)}$.[6]* **iii)** *If assumption A.3 holds then for any K^* compact subset of Θ, $n^{\frac{a-1}{a}}\left\|c_n'(\theta) - c_n^{*\prime}(\theta)\right\|_{K^*} \to 0$ P a.s., for $a = 2$ when $\mathbb{E}z_0^4 < +\infty$ or $a \in (1,2)$ when the analogous condition in ii) holds and therefore, if in the first case assumption A.2 holds additionally, then $n^{\frac{a-1}{a}}c_n^{*\prime}(\theta_0) \rightsquigarrow V_2$ and in the second case $n^{\frac{a-1}{a}}c_n^{*\prime}(\theta_0) \rightsquigarrow -V_a$.*

Proof. First due to the chain rule (that holds for one sided partial derivatives) we have that

$$-c_n'(\theta) = \frac{1}{n}\sum_{t=1}^{n}\left(\frac{y_t^2}{h_t(\theta)} - 1\right)\frac{h_t'(\theta)}{h_t(\theta)}$$

where h_t' is given in lemma 4.1 in the Appendix. Hence by exploiting the fact that $h_t(\theta_0) = \sigma_t^2$ P a.s. we obtain that

$$-c_n'(\theta_0) = \frac{1}{n}\sum_{t=1}^{n}(z_t^2 - 1)\frac{h_t'(\theta_0)}{\sigma_t^2}.$$

Then notice that the random element $\frac{h_t'(\theta_0)}{\sigma_t^2}$ is measurable with respect to $\mathcal{F}_{t-1} = \{z_{t-k}, k \geq 1\}$ and $\mathcal{F}_{t-1}$ is independent of z_t and $\mathbb{E}z_t^2 = 1$. **i)** Since $\mathbb{E}z_0^4 < +\infty$ and due to Lemma 4.1 the sequence $(\ell_t'(\theta_0))_{t\in\mathbb{N}}$ is a finite variance stationary ergodic zero-mean martingale difference sequence with respect to the filtration $(\mathcal{F}_{t-1})_{t\in\mathbb{N}}$. Consequently we can apply the central limit theorem for finite variance stationary ergodic martingale difference sequences to obtain the result. Furthermore

$$
\begin{aligned}
\mathbf{G}_0 &= \mathbb{E}\left[\ell_t'(\theta_0)(\ell_t'(\theta_0))^T\right] = \mathbb{E}\left[\frac{h_t'(\theta_0)(h_t'(\theta_0))^T}{\sigma_0^4}\right]\mathbb{E}\left[(z_t^2 - 1)^2\right] \\
&= \mathbb{E}\left[\frac{h_t'(\theta_0)(h_t'(\theta_0))^T}{\sigma_0^4}\right](\mathbb{E}z_t^4 - 1) = (\mathbb{E}z_t^4 - 1)\mathbf{J}
\end{aligned}
$$

By Lemma 4.6 and since $\mathbb{E}z_t^4 = \mathbb{E}(z_t^2)^2 > (\mathbb{E}z_t^2)^2$, it follows that $\mathbf{G}_0$ is a positive definite matrix. **ii)** The assumption on the asymptotic behavior of the distribution of z_0 is equivalent to

$$P\left(z_0^2 - 1 \leq x\right) = 1 - \frac{c_2 + o(1)}{x^a}h(x) \text{ as } x \to +\infty$$

---

[5]Remember that $h : \mathbb{R}^+ \to \mathbb{R}^+$ is slowly varying at infinity (in the Karamata's sense) if and only if for any $c > 0$, $\lim_{x\to\infty}\frac{h(cx)}{h(x)} = 1$.

[6]For the characterization of an a-stable random vector see also the definition (2.1) of Mikosch and Straumann [7].

Then due to Theorem 2.6.1 of Ibragimov and Linnik [5] it follows that the distribution of $z_0^2 - 1$ ($c_1 = 0$) lies in the domain of attraction of an a-stable distribution. Notice that this and Theorem 2.6.3 of Ibragimov and Linnik [5] imply that $\mathbb{E}(z_0^2)^\gamma < +\infty$ for any $1 \leq \gamma < a$. Then Theorem 2.6.5 of Ibragimov and Linnik [5] implies that in a neighborhood of the origin the characteristic function of $z_0^2 - 1$ is of the form $\exp\left(-c\,|\theta|^a\left(1 - i\beta\,\mathrm{sgn}\,(\theta)\tan\left(\frac{\pi a}{2}\right)\right)\right)$ where $c = -\frac{\Gamma(2-a)}{a-1}c_2\cos\left(\frac{\pi a}{2}\right)$ and $\beta = -1$. Then Theorem B.1 of Surgailis [13] along with lemma 4.1, the proof of lemma 4.7 and Theorem 2.6.1 of Straumann [12], imply that $-n^{\frac{a-1}{a}}\lambda^T c_n'(\theta_0)$ converges in distribution to an a-stable random variable for any non zero λ. The result follows by the Cramer-Wold device and the Continuous Mapping Theorem. **iii**) We have that P a.s.

$$n^{\frac{a-1}{a}}\left\|c_n'(\theta_0) - c_n^{*\prime}(\theta_0)\right\|_{K^*}$$

$$\leq \frac{1}{n^{\frac{1}{a}}}\sum_{t=1}^{n}\left\|\left(\frac{y_t^2}{h_t(\theta)} - 1\right)\frac{h_t'(\theta)}{h_t(\theta)} - \left(\frac{y_t^2}{h_t^*(\theta)} - 1\right)\frac{h_t^{*\prime}(\theta)}{h_t^*(\theta)}\right\|_{K^*}$$

$$\leq \frac{1}{n^{\frac{1}{a}}}\sum_{t=1}^{n}y_t^2\left|h_t^{-2}(\theta) - h_t^{-2*}(\theta)\right|_{K^*}\left\|h_t'(\theta) - h_t^{*\prime}(\theta)\right\|_{K^*}$$

$$+\frac{1}{n^{\frac{1}{a}}}\sum_{t=1}^{n}\left|h_t^{-1}(\theta) - h_t^{-1*}(\theta)\right|_{K^*}\left\|h_t'(\theta) - h_t^{*\prime}(\theta)\right\|_{K^*}$$

Exploiting the fact that h_t and h_t^* are P a.s. uniformly over t and any compact subset of Θ bounded away from zero we obtain from the mean value theorem that there exist positive constants c_1, c_2 for which the majorant side in the previous display is P a.s. less than or equal to

$$\frac{c_1}{n^{\frac{1}{a}}}\sum_{t=1}^{n}y_t^2\left|h_t(\theta) - h_t^*(\theta)\right|_{K^*}\left\|h_t'(\theta) - h_t^{*\prime}(\theta)\right\|_{K^*}$$

$$+\frac{c_2}{n^{\frac{1}{a}}}\sum_{t=1}^{n}\left|h_t(\theta) - h_t^*(\theta)\right|_{K^*}\left\|h_t'(\theta) - h_t^{*\prime}(\theta)\right\|_{K^*}$$

The first result follows from lemma 4.10, Proposition 5.2.12 of Straumann [12] which holds due to the definition of θ_0, assumption A.3, lemma 3.4 which enables Proposition 2.5.1 of Straumann [12] and the fact that in any case a is positive. The second result is a trivial consequence of the previous. ∎

The comparison between this CLT and Theorem 3.2 of Mikosch and Straumann [7] is as follows. Condition $P(z_0^2 - 1 \leq x) = 1 - \frac{c_2 + o(1)}{x^a}h(x)$ as $x \to +\infty$ is the analog to condition A.1 (regular variation) of Mikosch and Straumann [7] for $G_t = (z_t^2 - 1)$ and $Y_t = \frac{h_t'(\theta_0)}{\sigma_t^2}$. The present condition is not stronger than A.1 since the result of Breiman [3] appearing in Remark 3.4 of Mikosch and Straumann [7] along with lemma 4.1 implies that an analogous property holds for the distribution of $G_t Y_t$. This property is also implied by regular variation (see page 496 of Mikosch and Straumann [7]). Lemma 4.1 provides the analogy to the condition A.2. Finally our approach based on Theorem B.1 of Surgailis [13] essentially replaces condition A.3 with ergodicity for Y_t which is readily obtained due to the results in the proof of lemma 4.7 and Theorem 2.6.1 of Straumann [12]. In this respect we manage to avoid the verification of A.3 via some non readily established mixing condition (such as absolute regularity) for our model as compared to

ergodicity. Notice that Theorem B.1 of Surgailis [13] identifies the relevant normalization rate for the martingale transform series as $n^{-1/a}$. The present approach could also yield analogous results for other conditionally heteroskedastic models for which the verification of mixing is troublesome. Finally notice that given stationarity of Y_t (a prerequisite for both CLT's) *when A.3 is verified by the establishment of any kind of mixing implying regularity*, this also implies ergodicity. Hence in these cases our approach does not utilize stronger conditions than the one of Mikosch and Straumann [7].

Given the previous the following result is obtained by restricting the rate of convergence of the optimization error.

Proposition 3.8 *Under assumptions A.1, A.2, A.3 and if moreover $\varepsilon_n = o_p\left(n^{-2\left(\frac{a-1}{a}\right)}\right)$ then*

$$n^{\frac{a-1}{a}}\left(\theta_n - \theta_0\right) = O_p\left(1\right)$$

with $a = 2$ when $\mathbb{E}z_0^4 < \infty$ and $a \in (1,2)$ when $P\left(z_0 \in \left[-\sqrt{x+1}, \sqrt{x+1}\right]\right) = 1 - \frac{c_2 + o(1)}{x^a}h\left(x\right)$ as $x \to +\infty$, for $c_2 > 0$ and h as in proposition 3.7. In the second case assumption A.2 can be omitted.

Proof. First notice that by the definition of θ_n we have

$$\sum_{t=1}^{n}\ell_t^*\left(\theta_n\right) - \sum_{t=1}^{n}\ell_t^*\left(\theta_0\right) \leq o_p\left(n^{\frac{1-a}{a}}\right)$$

From lemma 3.6 and the definition of ℓ_t^* and h_t^* by employing Theorem 6 of Andrews [1], we have that since in any case $1 < a \leq 2$ the previous imply that

$$\nu_n^T \frac{1}{n^{\frac{1}{a}}} \sum_{t=1}^{n}\ell_t'^*\left(\theta_0\right) + \frac{1}{2}\nu_n^T c_t''^*\left(\theta_n^*\right)\nu_n \leq o_p\left(1\right)$$

where $\nu_n = n^{\frac{a-1}{a}}\left(\theta_n - \theta_0\right)$ and θ_n^* is a random element with values in the line segment between θ_n and θ_0 P a.s. which can stay outside K with positive probability. Obviously due to lemma 3.4 $\bar{\theta}_n$ converges to θ_0 P a.s. Using this we can choose $\varepsilon > 0$ so that lemma 4.5 holds and by additionally employing lemma 4.11 in the Appendix we have that the previous can be expressed as

$$\nu_n^T \frac{1}{n^{\frac{1}{a}}} \sum_{t=1}^{n}\ell_t'^*\left(\theta_0\right) + \frac{1}{2}\nu_n^T\left(\mathbb{E}\ell_0''\left(\theta_0\right) + o_p\left(1\right)\right)\nu_n \leq o_p\left(1\right)$$

Now notice that in the first case $(a = 2)$ assumption A.2 is explicitly put forward. In the second case $(a \in (1,2))$ assumption A.2 follows from the assumed behavior of the distribution of z_0. Hence in both cases lemma 4.6 holds, so we have that $\mathbb{E}\ell_0''\left(\theta_0\right)$ is a positive definite matrix and using this along with lemma 4.5. **iii**) we obtain that there exists some positive $c > 0$ such that

$$O_p\left(\|\nu_n\|\right) - c\|\nu_n\|^2 + \|\nu_n\|^2 o_p\left(1\right) \geq o_p\left(1\right)$$

which implies that

$$O_p\left(1\right) \geq \|\nu_n\|^2\left(1 + o_p\left(1\right)\right) - 2\|\nu_n\|\left(1 + o_p\left(1\right)\right)O_p\left(1\right) + O_p\left(1\right)$$

Hence

$$\|\nu_n\|\left(1 + o_p\left(1\right)\right) \leq O_p\left(1\right)$$

and the result follows. ∎

3.3 Asymptotic Distribution

In order to characterize the asymptotic distribution of $n^{\frac{a-1}{a}}(\theta_n - \theta_0)$ we first, following van der Vaart [16] (see paragraph 7.4), characterize the asymptotic parameter space as a convenient limit of the sequence of centered and rescaled parameter spaces and then impose some further structure in the assumption that follows. For a as in the previous section, we denote with $H_n(a)$ the $n^{\frac{a-1}{a}}(K - \theta_0) = \left\{ n^{\frac{a-1}{a}}(x - \theta_0), x \in K \right\}$ and notice that given the assumption A.1 $H_n(a)$ is compact and contains 0.

Definition D.5 $H(a) = \limsup_{n \to \infty} H_n(a)$ i.e. it is the set containing any $x \in \mathbb{R}^4$ such that x is a cluster point of some $(x_n)_{n \in \mathbb{N}}$ with $x_n \in H_n(a)$.

This is equivalent to that $x \in H(a)$ iff there exists an infinite subset of $\mathbb{N}$ (say $\mathcal{N}$) such that for any $\varepsilon > 0$, $H_n(a) \cap B(x, \varepsilon) \neq \varnothing$ for all $n \in \mathcal{N}$. Notice that $H(a)$ always exists and it is a closed subset of $\mathbb{R}^4$ (see Proposition 4.4 of Rockafellar and Wets [11]). In our case it is always different from $\varnothing$ since it contains 0. The last example in the list presented below implies that $H(a)$ generally depends on a.

Before stating the main proposition, it is probably useful to note that in the establishment of the rate of convergence, and/or of the asymptotic approximation of the shifted parameter space we do not follow the approach of Andrews [1]. This is either due to the fact that the Assumption 3 of the latter cannot be verified in our case when $a \neq 2$ and/or due to the fact that definition D.5 is *not less general* than Assumption 5 of Andrews [1]. This as well as a sufficient condition of independence of H from a are essentially implied by the following result.

Lemma 3.9 *Suppose that* Assumption 5 of Andrews [1] *holds for some closed cone* Λ. *Then* $H(a) = \Lambda$ *for any eligible* a.

Proof. Suppose that Assumption 5 of Andrews [1] holds, i.e. the sequence $n^{\frac{a-1}{a}} b_n^{-1}(K - \theta_0)$ is locally approximated by a closed cone Λ where $b_n \to \infty$ and $b_n \leq cn^{\frac{a-1}{a}}$ for some $0 < c < \infty$. Then notice that the cone Λ must be independent of the choice of a since $n^{\frac{a^*-1}{a^*}} b_n^{*-1}(K - \theta_0)$ is also locally approximated by Λ for $b_n^* = b_n n^{\frac{a^*-1}{a^*} - \frac{a-1}{a}} \leq cn^{\frac{a^*-1}{a^*}}$. Now let $x \in \Lambda / \{0\}$ and choose $x_n \equiv \frac{x}{b_n}$. Then $x_n \in \Lambda$ and $x_n = O(b_n^{-1})$. By construction $o(b_n^{-1}) = \operatorname{dist}\left(x_n, n^{\frac{a-1}{a}} b_n^{-1}(K - \theta_0)\right) = \|x_n - y_n\|$ for $y_n = n^{\frac{a-1}{a}} b_n^{-1} z_n$ and $z_n \in K - \theta_0$. Hence, $o(1) = \left\| x - n^{\frac{a-1}{a}} z_n \right\|$ and $n^{\frac{a-1}{a}} z_n \in n^{\frac{a-1}{a}}(K - \theta_0)$. Then from definition D.5 we have that $x \in H(a)$ and thereby $H(a) \supseteq \Lambda$. For the reverse inclusion suppose that $x \in H(a) / \{0\}$. This means that for some subsequence $x_{n_i} \in n_i^{\frac{a-1}{a}}(K - \theta_0)$ we have that $x_{n_i} \to x$. Then by construction we have that there exists a subsequence $\lambda_{n_i} \in \Lambda$ such that $\left\| \frac{x_{n_i}}{b_{n_i}} - \lambda_{n_i} \right\| = o(b_{n_i}^{-1})$. Hence $\left\| x_{n_i} - \lambda_{n_i}^* \right\| = o(1)$ for $\lambda_{n_i}^* = b_{n_i} \lambda_{n_i} \in \Lambda$. The triangle inequality implies that $\lambda_{n_i}^* \to x$. But Λ is closed so $x \in \Lambda$. Thereby when the approximation of Andrews holds, the approximating cone coincides with $H(a)$ which is independent of a. ∎

The next and final assumption enables the uniqueness part of the main result. This assumption is analogous to Assumption 6 of Andrews [1].

Assumption A.4 $H(a)$ *is convex.*

We can now state the main proposition of this section and then briefly discuss some examples.

Proposition 3.10 *Under assumptions A.1, A.2, A.3, A.4 and if moreover $\varepsilon_n = o_p\left(n^{-2\left(\frac{a-1}{a}\right)}\right)$, then*

$$n^{\frac{a-1}{a}}\left(\theta_n - \theta_0\right) \rightsquigarrow \tilde{h}$$

with $\tilde{h}$ defined uniquely by $q\left(\tilde{h}\right) = \inf_{h \in H(a)} q\left(h\right)$ and $q\left(h\right) := \left(h - \mathbf{J}^{-1}Z\right)' \mathbf{J}\left(h - \mathbf{J}^{-1}Z\right)$ for $\mathbf{J} = \mathbb{E}\ell_0''\left(\theta_0\right)$ positive definite, and using the notation and definitions and of lemma 3.7 i) $Z = V_2$ when $a = 2$ when $\mathbb{E}z_0^4 < \infty$ i.e. $Z \sim N\left(0, \left(\mathbb{E}z_t^4 - 1\right)\mathbf{J}\right)$ or ii) $Z = -V_a$ for $a \in (1,2)$ when $P\left(z_0 \in \left[-\sqrt{x+1}, \sqrt{x+1}\right]\right) = 1 - \frac{c_2 + o(1)}{x^a} h\left(x\right)$ as $x \to \infty$ and h slowly varying at infinity and $c_2 > 0$ where V_a follows the a-stable distribution characterized in lemma 3.7. In case ii) assumption A.2 can be omitted.

Proof. From lemma 3.6 and the definitions of the likelihoods in each of the cases described in the proposition, we can define $\varpi_n : \Theta \to \mathbb{R}$ as

$$
\begin{aligned}
\varpi_n\left(h\right) &\equiv n^{2\frac{a-1}{a}}\left(c_n^*\left(\theta_0 + n^{-\frac{a-1}{a}}h\right) - c_n^*\left(\theta_0\right)\right) \\
&= h' \frac{1}{n^{\frac{1}{a}}} \sum_{t=1}^n \ell_t'^*\left(\theta_0\right) + \frac{1}{2}h' c_t''^*\left(\theta_0\right)h + \frac{1}{2}h'\left(c_n''^*\left(\bar{\theta}_n\right) - c_n''^*\left(\theta_0\right)\right)h
\end{aligned}
$$

where $\bar{\theta}_n$ is a random element with values in the line segment between $n^{-\frac{a-1}{a}}h + \theta_0$ and θ_0 P a.s. that lies inside Θ. Obviously due to lemma 3.4 $\bar{\theta}_n$ converges to θ_0 P a.s. Using this we can choose $\varepsilon > 0$ so that lemma 4.5 holds and by additionally employing lemma 4.11 in the Appendix and lemma 3.7, we have that for U an arbitrary compact subset of Θ

$$\varpi_n(h) \rightsquigarrow h'Z - \frac{1}{2}h'\mathbf{J}h \text{ in } C\left(U, \mathbb{R}\right).$$

Hence for any A subset of Θ

$$\inf_{h \in A} \varpi_n\left(h\right) \rightsquigarrow \inf_{h \in A}\left(h'Z - \frac{1}{2}h'\mathbf{J}h\right) \tag{3}$$

Due to proposition 3.8 $h_n \doteq n^{\frac{a-1}{a}}\left(\theta_n - \theta_0\right) \in H_n\left(a\right) \cap B\left(0, n^{\frac{a-1}{a}}\varepsilon\right) \doteq H_n^*\left(a\right)$ with P-probability tending to 1 for some $\varepsilon > 0$. If F is a closed non empty subset of $\mathbb{R}^4$, and $h_n \in F$, then for large enough n, either $H_n^*\left(a\right) \subset F$, or $H_n^*\left(a\right) \not\subseteq F$ but $H_n^*\left(a\right) \cap F \neq \varnothing$. In either case due to the definitions of θ_n, ϖ_n and the fact that $\varepsilon_n = o_p\left(n^{-k}\right)$ for $k \geq 2 - \frac{2}{a}$

$$\inf_{h \in H_n^*(a) \cap F} \varpi_n\left(h\right) \leq \inf_{h \in H_n^*(a)} \varpi_n\left(h\right) + o_p\left(1\right)$$

and therefore due to Slutsky's lemma

$$
\begin{aligned}
P\left(h_n \in F\right) &\leq P\left(\inf_{h \in H_n^*(a) \cap F} \varpi_n\left(h\right) \leq \inf_{h \in H_n^*(a)} \varpi_n\left(h\right) + o_p\left(1\right)\right) \\
&\leq P\left(\inf_{h \in H_n^*(a) \cap F} \varpi_n\left(h\right) \leq \inf_{h \in H_n^*(a)} \varpi_n\left(h\right)\right) + o\left(1\right)
\end{aligned}
$$

Now notice that $H_n^* = H_n^* \cap \mathbb{R}^q$ and $\mathbb{R}^q$ is open, $\limsup_{n\to\infty} H_n^*(a) = H(a)$, since $\limsup_{n\to\infty} H_n(a) = H(a)$ and $n^{\frac{a-1}{a}} \to \infty$. Furthermore equation (3) and the continuous mapping theorem imply that Lemma 7.13.2-3 of van der Vaart [16] is applicable, so that the last probability is less than or equal to

$$P\left(\inf_{h\in H(a)\cap F} \varpi_n(h) \leq \inf_{h\in H(a)} \varpi_n(h) + o_p(1)\right) \leq P\left(\inf_{h\in H(a)\cap F} \varpi_n(h) \leq \inf_{h\in H(a)} \varpi_n(h)\right) + o(1)$$

due to Slutsky's Lemma. Now from equation 3, the continuous mapping theorem and Portmanteau Lemma we have that the $\limsup_{n\to\infty}$ of the probability in the right hand side of the last display is less than or equal to

$$P\left(\inf_{h\in H(a)\cap F} h'Z - \frac{1}{2}h'\mathbf{J}h \leq \inf_{h\in H(a)} h'Z - \frac{1}{2}h'\mathbf{J}h\right)$$

which equals

$$P\left(\inf_{h\in H(a)\cap F} h'Z + \frac{1}{2}h'\mathbf{J}h \pm \frac{1}{2}Z'\mathbf{J}^{-1}Z \leq \inf_{h\in H(a)} h'Z + \frac{1}{2}h'\mathbf{J}h \pm \frac{1}{2}Z'\mathbf{J}^{-1}Z\right)$$
$$= P\left(\inf_{h\in H(a)\cap F} \left(h - \mathbf{J}^{-1}Z\right)'\mathbf{J}\left(h - \mathbf{J}^{-1}Z\right) \leq \inf_{h\in H(a)} \left(h - \mathbf{J}^{-1}Z\right)'\mathbf{J}\left(h - \mathbf{J}^{-1}Z\right)\right)$$

Assumption A.4 implies that $H(a)$ is closed and convex, and lemma 4.6 that $\mathbf{J}$ is positive definite. Remember that this lemma holds since in the first case $(a = 2)$ assumption A.2 is explicitly put forward, while in the second case $(a \in (1,2))$ this assumption follows from the behavior of the distribution of z_0. Hence A.4 and 4.6 imply uniqueness for $\tilde{h}$, and thereby when

$$\inf_{h\in H(a)\cap F} \left(h - \mathbf{J}^{-1}Z\right)'\mathbf{J}\left(h - \mathbf{J}^{-1}Z\right) \leq \inf_{h\in H(a)} \left(h - \mathbf{J}^{-1}Z\right)'\mathbf{J}\left(h - \mathbf{J}^{-1}Z\right)$$

holds then

$$\tilde{h} \in H(a) \cap F$$

and therefore the last probability is less than or equal to

$$P\left(\tilde{h} \in H(a) \cap F\right) \leq P\left(\tilde{h} \in F\right)$$

hence we have proven that

$$\limsup_{n\to\infty} P\left(h_n \in F\right) \leq P\left(\tilde{h} \in F\right)$$

and the result follows from the Portmanteau theorem due to the fact that F is chosen arbitrarily. Notice that when $\mathbb{E}z_0^4 < \infty$ from lemma 3.7 we obtain that $a = 2$ and $Z \sim N\left(0, \left(\mathbb{E}z_t^4 - 1\right)\mathbf{J}\right)$ while from the same result when $a \in (1,2)$, $P\left(z_0 \in \left[-\sqrt{x+1}, \sqrt{x+1}\right]\right) = 1 - \frac{c_2+o(1)}{x^a}h(x)$ as $x \to \infty$, $c_2 > 0$ and h slowly varying at infinity $Z = -V_a$ which follows the a-stable distribution in the second case of lemma 3.7. ■

We close this paragraph by providing some examples concerning the form of K and the subsequent form of $H(a)$. Some of these have obvious econometric significance.

Example: interior point. Suppose that $\theta_0 \in \operatorname{Int} K$. This implies that there exists an open ball centered at θ_0 that lies entirely inside K. Then definition D.5 implies that $H(a) = \mathbb{R}^4$. Hence in the first case of the previous proposition $n^{\frac{a-1}{a}} (\theta_n - \theta_0) \rightsquigarrow N \left(0, (\mathbb{E}z_t^4 - 1) \mathbf{J}^{-1}\right)$ and in the second one $n^{\frac{a-1}{a}} (\theta_n - \theta_0) \rightsquigarrow -\mathbf{J}^{-1} V_a$.

Example: $\operatorname{GARCH}(1,1)$. Suppose that $\theta_0 = (\omega_0, \alpha_0, 0, \beta_0)$ and $K = [\omega_l, \omega_u] \times [\alpha_l, \alpha_u] \times [\gamma_l, 0] \times [0, \beta_u]$ where $0 < \omega_l < \omega_0 < \omega_u$, $0 < \alpha_l < \alpha_0 < \alpha_u$, $0 < \beta_0 < \beta_u$ and $\gamma_l < 0$. Then the centered parameter space is $K - \theta_0 = [\omega_l - \omega_0, \omega_u - \omega_0] \times [\alpha_l - \alpha_0, \alpha_u - \alpha_0] \times [\gamma_l, 0] \times [-\beta_0, \beta_u - \beta_0]$. Hence $H(a) = \mathbb{R}^2 \times \mathbb{R}^- \times \mathbb{R}$ and assumption A.4 holds. Given the econometric significance of the negative dynamic asymmetry, the result in the following proposition implies that the restriction of γ as above is asymptotically informative when $\gamma_0 = 0$.

Example: $\operatorname{QARCH}(1,1)$. Let $\theta_0 = (\omega_0, \alpha_0, \gamma_0, 0)$ and $K = [\omega_l, \omega_u] \times [\alpha_l, \alpha_u] \times [\gamma_l, 0] \times [0, \beta_u]$ where $0 < \omega_l < \omega_0 < \omega_u$, $0 < \alpha_0 < \alpha_u$, $\gamma_l < \gamma_0 < 0$ and $\beta_u > 0$. Then the centered parameter space is $K - \theta_0 = [\omega_l - \omega_0, \omega_u - \omega_0] \times [-\alpha_0, \alpha_u - \alpha_0] \times [\gamma_l - \gamma_0, -\gamma_0] \times [0, \beta_u]$ and $H(a) = \mathbb{R}^3 \times \mathbb{R}^+$, and again assumption A.4 holds.

Example: discrete K. Suppose that K is discrete hence due to assumption A.1 it is finite. Then $K - \theta_0$ is also finite and $H(a) = \{0\}$. Assumption A.4 holds and the previous proposition implies that in any of the two cases the asymptotic distribution is degenerate at 0.

Example: θ_0 lies on a sphere. Suppose that $\theta^* \in \operatorname{Int} \Theta$, $K = \bar{B}(\theta^*, \varepsilon)$ for $\varepsilon < \min(\omega^*, \alpha^*, |\gamma^*|, \beta^*, 1 - \beta^*)$, and $\|\theta_0 - \theta^*\| = \varepsilon$. Then $K - \theta_0 = \bar{B}(\theta^* - \theta_0, \varepsilon)$. Since $K - \theta_0$ is closed and convex there exists a supporting hyperplane of the translated parameter space at 0 and thereby $H(a)$ is the closed half space containing $K - \theta_0$ and the hyperplane. If $K = S(\theta^*, \varepsilon)$ then $H(a)$ equals the supporting hyperplane itself. In any case assumption A.4 holds.

Example: θ_0 lies on the boundary of an annulus. Suppose that θ^* and ε are as before, and $K = \bar{B}(\theta^*, \varepsilon) / B(\theta^*, \varepsilon_0)$ for $\varepsilon_0 < \varepsilon$, and $\|\theta_0 - \theta^*\| = \varepsilon_0$ or $\|\theta_0 - \theta^*\| = \varepsilon$. Suppose that $\|\theta_0 - \theta^*\| = \varepsilon$ and let $\mathcal{H}_\varepsilon$ denote the supporting hyperplane of $\bar{B}(\theta^* - \theta_0, \varepsilon)$ at 0 and $\mathcal{CH}_\varepsilon$ the closed half space containing $\bar{B}(\theta^* - \theta_0, \varepsilon)$ and $\mathcal{H}_\varepsilon$. In the first case $H(a) = \mathcal{CH}_\varepsilon^c \cup \mathcal{H}_\varepsilon$ and in the second $H(a) = \mathcal{CH}_\varepsilon$. In both cases assumption A.4 holds.

The following cases provide with counterexamples to assumption A.4.

Example: K is a union of line segments. Without loss of generality assume that $\theta_0 \in \operatorname{Int} \Theta$ and suppose that K is the union of a countable collection of line segments, each one of which contains θ_0 and lies inside $B(\theta_0, \delta)$ for $\delta < \inf_{y \in \operatorname{Bd} \Theta} \|\theta_0 - y\|$ where $\operatorname{Bd} \Theta$ denotes the boundary of Θ. Hence $K - \theta_0$ is the union of a countable collection of line segments which contain 0 and have length less than δ. $H(a)$ then equals the countable union of the one dimensional subspaces that are uniquely defined by each of the line segments in $K - \theta_0$. Obviously assumption A.4 holds iff all the initial line segments are colinear.

Example: K is comprised by the elements and the limit of a converging sequence. Let γ_m denote a real sequence that converges to zero and suppose without loss of generality that $\theta_0 = 0$. For some x in $\mathbb{R}^4$ let $K = K - \theta_0 = \{\gamma_m x, m \geq 1\} \cup \{0\}$. If for some $a^* \in (a, 2]$ $\gamma_m = O\left(m^{-a^*}\right)$ and $c = \lim_{m \to \infty} \gamma_m m^{a^*}$ then $H(a) = \begin{cases} \left\{\frac{c}{k^a} x, k = 1, 2, \ldots\right\} \cup \{0\} & \text{when } a = a^* \\ \{0\} & \text{when } a \neq a^* \end{cases}$.

Obviously in the first case assumption A.4 fails when $a = a^*$ if $x \neq 0$.

4 Further Research

We have examined the asymptotic properties of the QMLE of the $\mathrm{GQARCH}\,(1,1)$ model. Under our assumption framework, we established that the asymptotic distribution of $n^{\frac{a-1}{a}}\,(\mathrm{QMLE}-\theta_0)$ is characterized as the one of the unique minimizer of a quadratic form over a closed and convex subset of $\mathbb{R}^4$.[7] This represents the squared distance (w.r.t. a p.d. matrix) to a random vector that follows a normal distribution when $a = 2$ or is a linear transformation of an a-stable random vector when $a \in (1,2)$. When the parameter is an interior point this implies that we have distributional convergence to this random vector. Hence we have examined cases in which non normal asymptotic distributions are obtained either due to convergence of the estimator on the boundary of the parameter space, and/or due to the non existence of high order moments for random elements involved in this framework.

   The previous results raise two possible directions for further research. The first concerns the investigation of the conjecture that the necessary and sufficient conditions for stationarity and ergodicity of the $\mathrm{GARCH}\,(1,1)$ are sufficient for the $\mathrm{GQARCH}\,(1,1)$. The second concerns the derivation of the asymptotic distribution for several indirect estimators when the QMLE is used as an auxiliary in the same context. We expect that when θ_0 is a boundary point some of these estimators have "smaller" first order asymptotic mean (or in other cases median) bias and mse than the QMLE. We suspect that the derivation of those results could be facilitated by some locally uniform (w.r.t. θ_0) extension of the results presented above that moreover enables local quadratic approximations of the criteria without the use of derivatives and perhaps conditions that enable uniform integrability for $n^{\frac{a-1}{a}}\,(\mathrm{QMLE}-\theta_0)$.

Appendix

This section contains a sequence of intermediate technical lemmas used in the proofs of the main results of the paper. They are grouped according to their initial use in the establishment of the basic results in the paper. Some of them are actually used in more than one parts of the asymptotic theory. Lemma 3.6 in the main body of the paper enables the partial (possibly one sided) differentiation of any of the volatility filters over Θ. We denote the relevant mathematical entities according to the notation introduced in paragraph 3.2. In the following K^* denotes an arbitrary non empty subset of Θ. Remember that the notation $\|\cdot\|_{K^*}$ denotes $\sup_{K^*} \|\cdot\|$. Notice that separability and compactness of K^* imply measurability of $\sup_{K^*} \|\cdot\|$ (apply the Theorem of Measurable Projections in van der Vaart and Wellner [15], example 1.7.5 p. 47). Furthermore for $\varepsilon > 0$, $\overline{B}(\theta, \varepsilon)$ denotes the closed ball in $\mathbb{R}^4$ of radius ε, centered at θ.

Lemmata enabling the establishment of the rate of convergence of the ergodic QMLE.

Lemma 4.1 $\mathbb{E}\left\|\frac{h_t'(\theta)}{h_t(\theta)}\right\|_{K^*}^{\delta} < \infty$ for all $\delta > 0$.

Proof. Remember that h_t depends on θ_0 through y_{t-1}, $y_{t-2},...$ From lemma 3.1 we have that P a.s.

$$
h_t'(\theta) = \left(\frac{1}{1-\beta}, \quad -\frac{\gamma^2}{4\alpha^2(1-\beta)} + \sum_{i=0}^{\infty}\beta^i y_{t-i-1}^2, \quad \frac{\gamma}{2\alpha(1-\beta)} + \sum_{i=0}^{\infty}\beta^i y_{t-i-1}, \right.
$$
$$
\left. \frac{\omega}{(1-\beta)^2} + \sum_{i=0}^{\infty} i\beta^{i-1}\alpha\left(y_{t-i-1} + \frac{\gamma}{2\alpha}\right)^2 \right)'
$$

The first element of the vector $\frac{h_t'(\theta)}{h_t(\theta)}$ clearly uniformly bounded. For the second element note that $\forall \theta \in K$ there exist positive constants C_1, C_2 (possibly dependent on θ) so that $y_{t-i-1}^2 \leq C_1 + C_2\alpha\left(y_{t-i-1} + \frac{\gamma}{2\alpha}\right)^2$ for all i. This implies boundedness for the third element as well, observing that $|y_{t-i-1}| \leq 1 + y_{t-i-1}^2$. Due to compactness of K^* these bounds can be made uniform. As for the fourth element see Lemma 4.4. ∎

Lemma 4.2 $\mathbb{E}\left\|\frac{h_t''(\theta)}{h_t(\theta)}\right\|_{K^*}^{\delta} < \infty$ for all $\delta > 0$.

Proof. Notice first that continuity of the second order (possibly one sided) derivatives implies Young's theorem (see the proof of Theorem 6 of Andrews [1]). The result follows readily from Lemma 4.1 and Lemma 4.4 as P a.s.

$$
\frac{\partial^2 h_t(\theta)}{\partial\theta\partial\theta'} = \begin{pmatrix} 0 & 0 & 0 & \frac{1}{(1-\beta)^2} \\ & \frac{\gamma^2}{2\alpha^3(1-\beta)} & -\frac{\gamma}{2\alpha^2(1-\beta)} & -\frac{\gamma^2}{4\alpha^2(1-\beta)^2} + \frac{1}{1-\beta}\sum_{i=0}^{\infty}\beta^i y_{t-i-1}^2 \\ & & \frac{1}{2\alpha(1-\beta)} & \frac{\gamma}{2\alpha(1-\beta)^2} + \frac{1}{1-\beta}\sum_{i=0}^{\infty}\beta^i y_{t-i-1} \\ & & & \frac{2\omega}{(1-\beta)^3} + \sum_{i=0}^{\infty} i(i-1)\beta^{i-2}\alpha\left(y_{t-i-1} + \frac{\gamma}{2\alpha}\right)^2 \end{pmatrix}
$$

∎

21

Lemma 4.3 $\mathbb{E}\left(z_0^2\right)^\gamma < \infty$, *for some* γ *and*

$$\lim_{t \to 0} t^{-\mu} P\left(z_0^2 \le t\right) = 0, \quad \text{for some } \mu > 0$$

then for any $0 < \nu < \gamma$ *and some small enough* $\varepsilon > 0$

$$\mathbb{E}\left|\frac{\sigma_t^2}{h_t(\theta)}\right|^\nu_{\Theta \cap \overline{B}(\theta_0, \varepsilon)} < \infty.$$

Proof. Using $\gamma_0 y_{t-1} \le -\gamma_0\left(1 + y_{t-1}^2\right)$ we have

$$\frac{\sigma_t^2}{h_t(\theta)} \le \frac{\frac{\omega_0 - \gamma_0 + \frac{\gamma_0^2}{4\alpha_0}}{\sigma_{t-1}^2} + (\alpha_0 - \gamma_0) z_{t-1}^2 + \beta_0}{\frac{\omega + \frac{\gamma^2}{4\alpha}}{\sigma_{t-1}^2} + \alpha z_{t-1}^2 + \frac{\gamma z_{t-1}}{\sigma_{t-1}} + \beta \frac{h_{t-1}(\theta)}{\sigma_{t-1}^2}}$$

$$\le \frac{C_0 + (\alpha_0 - \gamma_0) z_{t-1}^2}{\displaystyle\inf_{\sigma_{t-1} \in \left[\sqrt{\omega_0/(1-\beta_0)}, +\infty\right)} \left(\frac{\omega + \frac{\gamma^2}{4\alpha}}{\sigma_{t-1}^2} + \frac{\gamma z_{t-1}}{\sigma_{t-1}} + \alpha z_{t-1}^2\right) + \beta \frac{h_{t-1}(\theta)}{\sigma_{t-1}^2}}$$

where $C_0 = \frac{\omega_0 - \gamma_0 + \frac{\gamma_0^2}{4\alpha_0}}{\inf \sigma_{t-1}^2} + \beta_0 = \frac{\omega_0 - \gamma_0 + \frac{\gamma_0^2}{4\alpha_0}}{\omega_0/(1-\beta_0)} + \beta_0$. Also $\displaystyle\inf_{\sigma_{t-1} \in \left[\sqrt{\omega_0/(1-\beta_0)}, +\infty\right)} \left(\frac{\omega + \frac{\gamma^2}{4\alpha}}{\sigma_{t-1}^2} + \frac{\gamma z_{t-1}}{\sigma_{t-1}} + \alpha z_{t-1}^2\right) =$

$\displaystyle\inf_{x \in \left(0, \sqrt{(1-\beta_0)/\omega_0}\right)} \left[\left(\omega + \frac{\gamma^2}{4\alpha}\right) x^2 + (\gamma z_{t-1}) x + \alpha z_{t-1}^2\right] = \frac{\alpha z_{t-1}^2}{\left(1 + \frac{\gamma^2}{4\omega\alpha}\right)}$. Therefore we can write

$$\frac{\sigma_t^2}{h_t(\theta)} \le \frac{C_0 + (\alpha_0 - \gamma_0) z_{t-1}^2}{C_1 z_{t-1}^2 + \beta \frac{h_{t-1}(\theta)}{\sigma_{t-1}^2}}$$

where $C_1 = \displaystyle\inf_{\theta \in K^*} \frac{\alpha}{\left(1 + \frac{\gamma^2}{4\omega\alpha}\right)} > 0$. Now if $\beta_0 = 0$ choose ε arbitrarily and obtain that $\displaystyle\sup_{\theta \in K^*} \frac{\sigma_t^2}{h_t(\theta)} \le \frac{C_0 + (\alpha_0 - \gamma_0) z_{t-1}^2}{C_1 z_{t-1}^2}$ so then skip to equation (4) setting $M = 1$ and the result follows using the same arguments. Now when $\beta_0 > 0$ choose ε small enough so that $\Theta \cap \overline{B}(\theta_0, \varepsilon)$ does not contain elements of Θ for which $\beta = 0$. This is always possible due to the fact that $\theta_0 \in K^*$ by assumption. Then there exists $K_1 > 0$ independent of θ so that

$$\frac{\sigma_t^2}{h_t(\theta)} \le \frac{K_1\left(1 + z_{t-1}^2\right)}{z_{t-1}^2 + \left(\frac{\sigma_{t-1}^2}{h_{t-1}(\theta)}\right)^{-1}}.$$

But

$$\left(\frac{\sigma_{t-1}^2}{h_{t-1}(\theta)}\right)^{-1} \ge \frac{z_{t-2}^2 + \left(\frac{\sigma_{t-2}^2}{h_{t-2}(\theta)}\right)^{-1}}{K_1\left(1 + z_{t-1}^2\right)}.$$

22

So, substituting

$$\frac{\sigma_t^2}{h_t(\theta)} \leq \frac{K_1^2 \prod_{i=1}^{2}\left(1 + z_{t-i}^2\right)}{K_1 z_{t-1}^2 + K_1 z_{t-1}^2 z_{t-2}^2 + z_{t-2}^2 + \left(\frac{\sigma_{t-2}^2}{h_{t-2}(\theta)}\right)^{-1}}$$

$$\leq \frac{K_1^2 \prod_{i=1}^{2}\left(1 + z_{t-i}^2\right)}{K_1 z_{t-1}^2 + z_{t-2}^2 + \left(\frac{\sigma_{t-2}^2}{h_{t-2}(\theta)}\right)^{-1}}$$

Hence recursively

$$\frac{\sigma_t^2}{h_t(\theta)} \leq \frac{K_1^M \prod_{i=1}^{M}\left(1 + z_{t-i}^2\right)}{K_2 \sum_{i=1}^{M} z_{t-i}^2}, \text{ for any } M \geq 1 \tag{4}$$

where K_2 some constant dependent on K_1 and M. Finally following the remaining steps of Lemma 5.1 of Berkes et al. [2] we obtain the result. ∎

Lemma 4.4 $\mathbb{E}\left\|\frac{\sum_{i=0}^{\infty} i^3 \beta^i y_{t-i-1}^2}{1 + \sum_{i=0}^{\infty} \beta^i y_{t-i-1}^2}\right\|_{K^*}^{v} < \infty$ *for any* $v > 0$.

Proof. First notice that the results of lemma 3.4 would hold even if the ergodic θ_0 did not belong to the examined compact subset of Θ. From this lemma there exists $\delta > 0$ so that $\mathbb{E}\left(y_0^2\right)^\delta < \infty$. Then, along the lines of the proof of Lemma 5.2 of Berkes et al. [2], replacing $c_i(u)$ with β^i and noting that we can choose $\beta < \rho_* < 1 \ \forall \beta \in K^*$ and $M \geq M_0(\rho)$ large enough so that $i\beta^i < \rho^i$ for $i \geq M$. For any $M \geq 1$, the result follows. ∎

Lemma 4.5 *For ε as in the previous lemma, if $\mathbb{E}\left(z_0^2\right)^\delta < +\infty$ for some $\delta > 1$ then for all $\gamma_n \to 0$*

$$\sup_{\theta \in \Theta \cap \overline{B}(\theta_0,\varepsilon):\|\theta-\theta_0\|\leq\gamma_n} \left\|c_n''(\theta) - \mathbb{E}\ell_0''(\theta)\right\| = o_p(1).$$

Proof. We have that with P probability one

$$c_n''(\theta) = \frac{1}{n}\sum_{t=1}^{n}\left[\left(\frac{2y_t^2}{h_t(\theta)} - 1\right)\frac{h_t'(\theta)\left[h_t'(\theta)\right]^T}{(h_t(\theta))^2} + \left(1 - \frac{y_t^2}{h_t(\theta)}\right)\frac{h_t''(\theta)}{h_t(\theta)}\right].$$

By Straumann [12] Propositions 5.2.12, 5.5.1 and 5.5.2 together with Proposition 2.1.1, (c_n'') is a stationary ergodic sequence of random elements with values in $\mathbb{C}\left(\Theta \cap \overline{B}(\theta_0,\varepsilon), \mathbb{R}^{4\times4}\right)$, with

$$\left\|\ell_0''(\theta)\right\|_{\Theta\cap\overline{B}(\theta_0,\varepsilon)} \leq \left\|\frac{h_0'}{h_0}\right\|_{\Theta\cap\overline{B}(\theta_0,\varepsilon)}^2 \left(2\left|\frac{y_0^2}{h_0}\right|_{\Theta\cap\overline{B}(\theta_0,\varepsilon)} + 1\right) + \left\|\frac{h_0''}{h_0}\right\|_{\Theta\cap\overline{B}(\theta_0,\varepsilon)}\left(1 + \left|\frac{y_0^2}{h_0}\right|_{\Theta\cap\overline{B}(\theta_0,\varepsilon)}\right)$$

By an application of the Hölder inequality together with Lemmas 4.1, 4.2, 4.3 enabled by $\mathbb{E}\left(z_0^2\right)^\delta < +\infty$ we have that $\mathbb{E}\left\|\ell_0''(\theta)\right\|_{\Theta\cap\overline{B}(\theta_0,\varepsilon)} < +\infty$ and the fact that $\Theta \cap \overline{B}(\theta_0,\varepsilon)$ is compact. Then by the stationarity-ergodicity of $\left(\ell_t''(\theta)\right)_{t\in\mathbb{Z}}$, we apply Theorem 2.2.1 of Straumann [12] to obtain the result. ∎

Lemma 4.6 *Under assumption A.2* $\mathbf{J}=\mathbb{E}\left[\ell_0''(\theta)\right] = \mathbb{E}\left[\frac{h_0'(\theta_0)\left(h_0'(\theta_0)\right)^T}{\sigma_0^4}\right]$ *is a positive definite matrix.*

Proof. Using Straumann's [12] Lemma 5.6.3, we require that the components of the vector $\left(1, -\frac{\gamma^2}{4\alpha^2}+y, y_0, \sigma_0^2\right)'$ are linearly independent random variables. Suppose not, i.e. there exist $\lambda_1, \lambda_2, \lambda_3, \lambda_4 \in \mathbb{R}$ where $(\lambda_1, \lambda_2, \lambda_3, \lambda_4)' \neq \mathbf{0}_{4\times 1}$ such that:

$$\lambda_1 - \frac{\lambda_2\gamma^2}{4\alpha^2} + \lambda_2 y_0^2 + \lambda_3 y_0 + \lambda_4 \sigma_0^2 = 0.$$

By Lemma 3.3, the only solution to this equation is the zero vector. ∎

Lemmata enabling the establishment of the asymptotic equivalence between the ergodic and the non-ergodic QMLE. In the following the symbol $\overset{e.a.s.}{\to}$ denotes experientially almost sure convergence (w.r.t. P) as defined in Section 2.5 of Straumann [12]. For economy of space we also denote with $\overset{a.s.}{\to}$ almost sure convergence (w.r.t. P).

Lemma 4.7 $\left\|h_t'(\theta) - h_t'^*(\theta)\right\|_{K^*} \overset{e.a.s.}{\to} 0.$

Proof. We proceed elementwise. We identify the SRE that each (possibly one sided) partial derivatives satisfy and then use Proposition 5.2.12. of Straumann [12]. In our case it is easy to see that the one sided partial derivatives will be identical to the two sided ones.

- For ω we have that $\frac{\partial h_t}{\partial \omega} = 1 + \beta\frac{\partial h_{t-1}}{\partial \omega} = \sum_{i=0}^{m} \beta^i + \beta^{m+1}\frac{\partial h_{t-m-1}}{\partial \omega} \overset{m\to\infty}{\to} \frac{1}{1-\beta}$ P a.s., hence the SRE $s_{t+1} = \Phi(s_t)$, $t \in \mathbb{Z}$ for which $[\Phi(s)](\beta) = 1 + \beta s$, $\ln^+\Lambda(\Phi) = \ln^+\beta < \infty$ and $\mathbb{E}\ln\Lambda(\Phi(s)) = \ln\beta < 0$, $\mathbb{E}\ln^+\left\|\Phi(s)(\varsigma_0^2)\right\|_{K^*} = \mathbb{E}\ln^+\left\|1 - \beta\varsigma_0^2\right\|_{K^*} < \infty$. Then, by Proposition 5.2.12. of Straumann [12] we have that

  $\left\|\frac{\partial h_t^*(\theta)}{\partial \omega} - \frac{\partial h_t(\theta)}{\partial \omega}\right\|_{K^*} \overset{e.a.s.}{\to} 0$ and $\frac{\partial h_t}{\partial \omega} = \frac{1}{1-\beta}$ P a.s.

- For α we have that $\frac{\partial h_t}{\partial \alpha} = y_{t-1}^2 - \frac{\gamma^2}{4\alpha^2} + \beta\frac{\partial h_{t-1}}{\partial \alpha} = \sum_{i=0}^{\infty} \beta^i\left(-\frac{\gamma^2}{4\alpha^2} + y_{t-i-1}^2\right) = -\sum_{i=0}^{\infty}\beta^i\frac{\gamma^2}{4\alpha^2} +$

  $\sum_{i=0}^{\infty}\beta^i y_{t-i-1}^2 = -\frac{\gamma^2}{4\alpha^2(1-\beta)} + \sum_{i=0}^{\infty}\beta^i y_{t-i-1}^2$ P a.s., hence the SRE: $s_{t+1} = \Phi_t(s_t)$, where $[\Phi_t(s)](\beta) = y_{t-1}^2 - \frac{\gamma^2}{4\alpha^2} + \beta s$ and $\ln^+\Lambda(\Phi_t) = \ln^+\beta < \infty$, $\mathbb{E}\ln\Lambda(\Phi_t) = \mathbb{E}\ln\beta = \ln\beta < 0$, $\mathbb{E}\ln^+\left\|\Phi_t(\varsigma_0^2)\right\| = \mathbb{E}\ln^+\left\|y_{t-1}^2 - \frac{\gamma^2}{4\alpha^2} - \beta\varsigma_0^2\right\|_{K^*} < \infty$. So, by Proposition 5.2.12. of Straumann [12] we have that

  $\left\|\frac{\partial h_t^*(\theta)}{\partial \alpha} - \frac{\partial h_t(\theta)}{\partial \alpha}\right\|_{K^*} \overset{e.a.s.}{\to} 0$ and $\frac{\partial h_t(\theta)}{\partial \alpha} = -\frac{\gamma^2}{4\alpha^2(1-\beta)} + \sum_{i=0}^{\infty}\beta^i y_{t-i-1}^2$ P a.s.

- For γ we have that $\frac{\partial h_t(\theta)}{\partial \gamma} = \frac{\gamma}{2\alpha(1-\beta)} + \sum_{i=0}^{\infty}\beta^i y_{t-i-1}^2$ P a.s., hence the SRE: $s_{t+1} = \Phi_t(s_t)$, for which $\ln^+\Lambda(\Phi_t) = \ln^+\beta < \infty$ and $\mathbb{E}\ln\Lambda(\Phi_t) = \mathbb{E}\ln\beta = \ln\beta < 0$, $\mathbb{E}\ln^+\left|\Phi_t(\varsigma_0^2)\right| =$

$\mathbb{E}\ln^+\left|y_{t-1}-\frac{\gamma}{2\alpha}-\beta\varsigma_0^2\right|_{K^*} \le \ln 2 + \mathbb{E}\ln^+|y_{t-1}| + \mathbb{E}\ln^+\left|\frac{\gamma}{2\alpha}+\beta\varsigma_0^2\right|_{K^*} < \infty$. So, by Proposition 5.2.12. of Straumann [12] we have that

$$\left\|\frac{\partial h_t^*(\theta)}{\partial\gamma}-\frac{\partial h_t(\theta)}{\partial\gamma}\right\|_{K^*} \overset{e.a.s.}{\to} 0 \text{ and } \frac{\partial h_t(\theta)}{\partial\gamma} = \frac{\gamma}{2\alpha(1-\beta)}+\sum_{i=0}^{\infty}\beta^i y_{t-i-1} \; P \text{ a.s.}$$

- For β we have that $\frac{\partial h_t(\theta)}{\partial\beta} = h_{t-1}(\theta)+\beta\frac{\partial h_t(\theta)}{\partial\beta^+} = \sum_{i=0}^{\infty}\beta^i h_{t-i-1}(\theta) \; P$ a.s., hence the SRE: $s_{t+1}=\Phi(s_t)$, for which $\ln^+\Lambda(\Phi)=\ln^+\beta<\infty$ and $\mathbb{E}\ln\Lambda(\Phi)=\mathbb{E}\ln\beta=\ln\beta<0$, $\mathbb{E}\ln^+|\Phi(\varsigma_0^2)|=\mathbb{E}\ln^+\left|h_{t-1}^*(\theta)+\beta\varsigma_0^2\right| \le \ln 2+\mathbb{E}\ln^+\left|h_{t-1}^*(\theta)\right|+\ln^+\beta\varsigma_0^2<\infty$. So, by Proposition 5.2.12. of Straumann [12] we have that $\left\|\frac{\partial h_t^*(\theta)}{\partial\beta}-\frac{\partial h_t(\theta)}{\partial\beta}\right\|_{K^*}\overset{e.a.s.}{\to} 0$ and $\frac{\partial h_t(\theta)}{\partial\beta}=h_{t-1}(\theta)+\beta\frac{\partial h_t(\theta)}{\partial\beta}=\sum_{i=0}^{\infty}\beta^i h_{t-i-1}(\theta)$ a.s. Then using Proposition 2.5.1 of Straumann [12], since $\beta^i \overset{e.a.s.}{\to} 0$ as $i\to\infty$ (choose e.g. $\gamma=\beta^{-\frac{1}{2}}>1$ to see that $\gamma^i\beta^i\overset{a.s.}{\to} 0$) and $y_{t-i-1}^2, y_{t-i-1}, h_{t-1}(\theta)$ are ergodic with $\ln^+ y_{t-i-1}^2<\infty$, $\ln^+|y_{t-i-1}|<\infty$, $\ln^+ h_{t-i-1}(\theta)<\infty$ we have that $\sum_{i=0}^{\infty}\beta^i y_{t-i-1}^2, \sum_{i=0}^{\infty}\beta^i y_{t-i-1}, \sum_{i=0}^{\infty}\beta^i h_{t-i-1}(\theta)$ converge $e.a.s.$ Thus, $\frac{\partial h_t(\theta)}{\partial\theta}$ is well defined.

∎

Lemma 4.8 $\|h_t''(\theta)-h_t''^*(\theta)\|_{K^*}\overset{e.a.s.}{\to} 0$

Proof. We proceed elementwise as in the previous proof. For economy of space we present only two cases. The others follow analogously. Consider first the $\frac{\partial^2 h_t(\theta)}{\partial\alpha\partial\omega}=\beta\frac{\partial^2 h_{t-1}(\theta)}{\partial\alpha\partial\omega}$. We have the SRE: $s_{t+1}=\Phi(s_t)$, for which $\ln^+\Lambda(\Phi)=\ln^+\beta<\infty$ and $\mathbb{E}\ln\Lambda(\Phi)=\mathbb{E}\ln\beta=\ln\beta<0$. $\mathbb{E}\ln^+\|\Phi(\varsigma_0^2)\|_{K^*}=\mathbb{E}\ln^+\|\beta\varsigma_0^2\|_K<\infty$. So, by Proposition 5.2.12. of Straumann we have that $\left\|\frac{\partial^2 h_t^*(\theta)}{\partial\alpha\partial\omega}-\frac{\partial^2 h_t(\theta)}{\partial\alpha\partial\omega}\right\|_{K^*}\overset{e.a.s.}{\to} 0$. Consider finally $\frac{\partial^2 h_t(\theta)}{\partial\alpha\partial\beta}$. We obtain that

$$
\begin{aligned}
\left\|\frac{\partial^2 h_t^*(\theta)}{\partial\alpha\partial\beta}-\frac{\partial^2 h_t(\theta)}{\partial\alpha\partial\beta}\right\|_{K^*} &= \left\|\frac{\partial h_{t-1}^*(\theta)}{\partial\alpha}-\frac{\partial h_{t-1}(\theta)}{\partial\alpha}+\beta\frac{\partial h_{t-1}^*(\theta)}{\partial\alpha\partial\beta^+}-\beta\frac{\partial h_{t-1}(\theta)}{\partial\alpha\partial\beta^+}\right\| \\
&\le \left\|\frac{\partial h_{t-1}^*(\theta)}{\partial\alpha}-\frac{\partial h_{t-1}(\theta)}{\partial\alpha}\right\|+\beta\left\|\frac{\partial h_{t-1}^*(\theta)}{\partial\alpha\partial\beta^+}-\frac{\partial h_{t-1}(\theta)}{\partial\alpha\partial\beta^+}\right\| \\
&\le \sum_{i=0}^{\infty}\beta^i\left\|\frac{\partial h_{t-i-1}^*(\theta)}{\partial\alpha}-\frac{\partial h_{t-i-1}(\theta)}{\partial\alpha}\right\|\overset{e.a.s.}{\to} 0.
\end{aligned}
$$

∎

Lemma 4.9 $\left\|h_t^{*\prime}(\theta)\,h_t^{*\prime}(\theta)^T-h_t'(\theta)\,h_t'(\theta)^T\right\|_{K^*}\overset{e.a.s.}{\to} 0$

Proof. Trivial. ∎

Lemma 4.10 $n \left\| c_n'^* (\theta) - c_n'(\theta) \right\|_{K^*}$ converges P a.s.

Proof. By an application of the mean value theorem to the function $f(a,b) = \frac{a}{b} \left(1 - \frac{y_t^2}{b} \right)$, $a \in \mathbb{R}$, $b > 0$, due to remark R.4, we obtain

$$
\begin{aligned}
\left\| \ell_t^{*\prime}(\theta) - \ell_t'(\theta) \right\|_{K^*} &= \left\| \left(1 - \frac{y_t^2}{h_t^*} \right) \frac{h_t^{*\prime}}{h_t^*} - \left(1 - \frac{y_t^2}{h_t} \right) \frac{h_t'}{h_t} \right\|_{K^*} \\
&\leq c \left(1 + y_t^2 \right) \left[\left\| h_t - h_t^* \right\|_{K^*} + \left\| h_t' - h_t^{*\prime} \right\|_{K^*} \right]
\end{aligned}
$$

for some $c > 0$. Then, by Proposition 5.2.12 of Straumann [12], $\left\| h_t - h_t^* \right\|_K \overset{e.a.s.}{\to} 0$, and by lemma 4.7 $\left\| h_t' - h_t^{*\prime} \right\|_K \overset{e.a.s.}{\to} 0$ so $\left[\left\| h_t - h_t^* \right\|_K + \left\| h_t' - h_t^{*\prime} \right\|_K \right] \overset{e.a.s.}{\to} 0$. Then, lemma 3.4 implies that $E \ln^+ \left[c \left(1 + y_t^2 \right) \right] < \infty$ by Lemma 2.5.3 of Straumann [12]. Then

$$
n \left\| c_n'^* (\theta) - c_n'(\theta) \right\|_{K^*} \leq \sum_{t=1}^{\infty} \left\| \ell_t^{*\prime}(\theta) - \ell_t'(\theta) \right\|_{K^*} < \infty
$$

and the result is obtained by an application of Proposition 2.5.1 of Straumann [12]. ∎

Lemma 4.11 $\left\| c_n^{*\prime\prime}(\theta) - c_n''(\theta) \right\|_{K^*} \overset{a.s.}{\to} 0.$

Proof. Using the definitions of the second order (possibly one sided) derivatives, the triangle inequality and applying the mean value theorem to the functions $f(a,b) = \frac{a}{b} \left(1 - \frac{y_t^2}{b} \right)$ and $g(a,b) = \left(\frac{2y_t^2}{a} - 1 \right) \frac{b}{a^2}$, we obtain

$$
\begin{aligned}
& \left\| \ell_t^{*\prime\prime}(\theta) - \ell_t''(\theta) \right\|_{K^*} \\
\leq \; & \left\| \left(1 - \frac{y_t^2}{h_t^*} \right) \frac{h_t^{*\prime\prime}}{h_t^*} - \left(1 - \frac{y_t^2}{h_t} \right) \frac{h_t''}{h_t} \right\|_{K^*} \\
& + \left\| \left(\frac{2y_t^2}{h_t^*} - 1 \right) \frac{1}{(h_t^*)^2} h_t^{*\prime} (h_t^{*\prime})^T - \left(\frac{2y_t^2}{h_t} - 1 \right) \frac{1}{(h_t)^2} h_t' (h_t')^T \right\|_{K^*} \\
\leq \; & c_1 \left(1 + y_t^2 \right) \left[\left\| h_t - h_t^* \right\|_{K^*} + \left\| h_t^{*\prime\prime} - h_t'' \right\|_{K^*} \right] \\
& + c_2 \left(1 + y_t^2 \right) \left[\left\| h_t - h_t^* \right\|_{K^*} + \left\| h_t^{*\prime} (h_t^{*\prime})^T - h_t' (h_t')^T \right\|_{K^*} \right]
\end{aligned}
$$

for some $c_1, c_2 > 0$ which exist due to compactness of K^* and the uniform boundedness of the volatility filters away from zero. Then, by Proposition 5.2.12 of Straumann [12], $\left\| h_t - h_t^* \right\|_{K^*} \overset{e.a.s.}{\to} 0$, by Lemma 4.8 $\left\| h_t'' - h_t^{*\prime\prime} \right\|_{K^*} \overset{e.a.s.}{\to} 0$ and by Lemma 4.9 $\left\| h_t^{*\prime} (h_t^{*\prime})^T - h_t' (h_t')^T \right\|_{K^*}$, so analogously to the proof of Lemma 4.10 we obtain

$$
n \left\| c_n''(\theta) - c_n^{*\prime\prime}(\theta) \right\|_{K^*} \leq \sum_{t=1}^{\infty} \left\| \ell_t''(\theta) - \ell_t^{*\prime\prime}(\theta) \right\|_{K^*} < \infty.
$$

∎
